**ABSTRACT**

An apparatus, which includes a first electronic device, a first  
nonlinear capacitance compensation circuit, and a capaci-  
tance compensation control circuit, is disclosed. The first  
electronic device has a first nonlinear capacitance and is  
coupled to the first nonlinear capacitance compensation  
circuit, which has a first compensation capacitance and  
receives a first compensation control signal. The capacitance  
compensation control circuit adjusts the first compensation  
capacitance using the first compensation control signal to at  
least partially linearize the first nonlinear capacitance.

## NONLINEAR CAPACITANCE LINEARIZATION

### RELATED APPLICATIONS

The present application claims priority to U.S. Provisional Patent Application No. 61/831,666, filed Jun. 6, 2013; U.S. Provisional Patent Application No. 61/860,932, filed Aug. 1, 2013; U.S. Provisional Patent Application No. 61/909,028, filed Nov. 26, 2013; U.S. Provisional Patent Application No. 61/938,884, filed Feb. 12, 2014; U.S. Provisional Patent Application No. 61/949,581, filed Mar. 7, 2014; U.S. Provisional Patent Application No. 61/951,844, filed Mar. 12, 2014; U.S. Provisional Patent Application No. 61/982,946, filed Apr. 23, 2014; U.S. Provisional Patent Application No. 61/982,952, filed Apr. 23, 2014; U.S. Provisional Patent Application No. 61/982,971, filed Apr. 23, 2014; and U.S. Provisional Patent Application No. 62/008,192, filed Jun. 5, 2014.

The present application is related to concurrently filed U.S. patent application Ser. No. 14/298,829, entitled "TUNABLE RF FILTER STRUCTURE FORMED BY A MATRIX OF WEAKLY COUPLED RESONATORS;" concurrently filed U.S. patent application Ser. No. 14/298,830, entitled "TUNABLE RF FILTER PATHS FOR TUNABLE RF FILTER STRUCTURES;" now U.S. Pat. No. 9,419,578; concurrently filed U.S. patent application Ser. No. 14/298,834, entitled "HIGH QUALITY FACTOR INTERCONNECT FOR RF CIRCUITS;" concurrently filed U.S. patent application Ser. No. 14/298,863, entitled "TUNABLE RF FILTER BASED RF COMMUNICATIONS SYSTEM;" and concurrently filed U.S. patent application Ser. No. 14/298,852, entitled "MULTI-BAND INTERFERENCE OPTIMIZATION."

All of the applications listed above are hereby incorporated herein by reference in their entireties.

### FIELD OF THE DISCLOSURE

Embodiments of the present disclosure relate to radio frequency (RF) communications systems, which may include RF front-end circuitry, RF transceiver circuitry, RF amplifiers, direct current (DC)-DC converters, RF filters, RF antennas, RF switches, RF combiners, RF splitters, the like, or any combination thereof.

### BACKGROUND

As wireless communications technologies evolve, wireless communications systems become increasingly sophisticated. As such, wireless communications protocols continue to expand and change to take advantage of the technological evolution. As a result, to maximize flexibility, many wireless communications devices must be capable of supporting any number of wireless communications protocols, each of which may have certain performance requirements, such as specific out-of-band emissions requirements, linearity requirements, or the like. Further, portable wireless communications devices are typically battery powered and need to be relatively small, and have low cost. As such, to minimize size, cost, and power consumption, RF circuitry in such a device needs to be as simple, small, flexible, and efficient as is practical. Thus, there is a need for RF circuitry in a communications device that is low cost, small, simple, flexible, and efficient.

### SUMMARY

An apparatus, which includes a first electronic device, a first nonlinear capacitance compensation circuit, and a

2

capacitance compensation control circuit, is disclosed according to one embodiment of the present disclosure. The first electronic device has a first nonlinear capacitance and is coupled to the first nonlinear capacitance compensation circuit, which has a first compensation capacitance and receives a first compensation control signal. The capacitance compensation control circuit adjusts the first compensation capacitance using the first compensation control signal to at least partially linearize the first nonlinear capacitance.

Those skilled in the art will appreciate the scope of the disclosure and realize additional aspects thereof after reading the following detailed description in association with the accompanying drawings.

### BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings incorporated in and forming a part of this specification illustrate several aspects of the disclosure, and together with the description serve to explain the principles of the disclosure.

FIG. 1 shows traditional communications circuitry according to the prior art.

FIG. 2 shows the traditional communications circuitry according to the prior art.

FIG. 3 shows the traditional communications circuitry according to the prior art.

FIG. 4 shows RF communications circuitry according to one embodiment of the RF communications circuitry.

FIG. 5 is a graph illustrating filtering characteristics of a first tunable RF filter path and a second tunable RF filter path illustrated in FIG. 4 according to one embodiment of the first tunable RF filter path and the second tunable RF filter path.

FIGS. 6A and 6B are graphs illustrating filtering characteristics of the first tunable RF filter path and the second tunable RF filter path, respectively, illustrated in FIG. 4 according to an alternate embodiment of the first tunable RF filter path and the second tunable RF filter path, respectively.

FIG. 7 shows the RF communications circuitry according to one embodiment of the RF communications circuitry.

FIG. 8 shows the RF communications circuitry according to an alternate embodiment of the RF communications circuitry.

FIGS. 9A and 9B are graphs illustrating filtering characteristics of the first tunable RF filter path and the second tunable RF filter path, respectively, illustrated in FIG. 8 according to an additional embodiment of the first tunable RF filter path and the second tunable RF filter path.

FIGS. 10A and 10B are graphs illustrating filtering characteristics of a first traditional RF duplexer and a second traditional RF duplexer, respectively, illustrated in FIG. 3 according to the prior art.

FIG. 11 shows the RF communications circuitry according to one embodiment of the RF communications circuitry.

FIG. 12 shows the RF communications circuitry according to an alternate embodiment of the RF communications circuitry.

FIG. 13 shows the RF communications circuitry according to an additional embodiment of the RF communications circuitry.

FIG. 14 shows the RF communications circuitry according to another embodiment of the RF communications circuitry.

FIG. 15 shows the RF communications circuitry according to a further embodiment of the RF communications circuitry.

FIG. 16 shows the RF communications circuitry according to one embodiment of the RF communications circuitry.

FIG. 17 shows the RF communications circuitry according to an alternate embodiment of the RF communications circuitry.

FIG. 18 shows the RF communications circuitry according to an additional embodiment of the RF communications circuitry.

FIG. 19 shows the RF communications circuitry according to another embodiment of the RF communications circuitry.

FIG. 20 shows the RF communications circuitry according to a further embodiment of the RF communications circuitry.

FIG. 21 illustrates one embodiment of a tunable radio frequency (RF) filter structure that defines multiple tunable RF filtering paths that are independent of each other.

FIG. 22 illustrates another embodiment of a tunable RF filter path shown in FIG. 21 having cross-coupling capacitors arranged in a V-bridge structure.

FIG. 23 illustrates another embodiment of the tunable RF filter path shown in FIG. 21 having cross-coupling capacitors arranged in an X-bridge structure.

FIG. 24 illustrates another embodiment of the tunable RF filter path shown in FIG. 21 having a cross-coupling capacitor arranged in a single positive bridge structure.

FIG. 25 illustrates another embodiment of the tunable RF filter path shown in FIG. 21 having cross-coupling capacitors arranged in an H-bridge structure.

FIG. 26 illustrates another embodiment of the tunable RF filter path shown in FIG. 21 having cross-coupling capacitors arranged in a double H-bridge structure.

FIG. 27 illustrates another embodiment of the tunable RF filter path shown in FIG. 21 having four weakly coupled resonators with magnetic and electric couplings between them.

FIGS. 28A-28D disclose different embodiments of a tunable RF filter structure, each with a different number of input terminals and output terminals.

FIG. 29 illustrates one embodiment of a tunable radio frequency (RF) filter structure having four resonators and cross-coupling capacitive structures electrically connected between the four resonators so as to form a 2x2 matrix with the four resonators. In alternative embodiments, fewer (e.g., three) resonators or more (e.g., five or more) resonators may be provided.

FIG. 30 illustrates another embodiment of a tunable RF filter structure having M number of rows and N number of columns of resonators that are electrically connected by cross-coupling capacitive structures so that the tunable RF filter structure is arranged so as to form an MxN two-dimensional matrix of the resonators.

FIG. 31 illustrates the tunable RF filter structure shown in FIG. 30 electrically connected to various RF antennas.

FIG. 32 illustrates the tunable RF filter structure shown in FIG. 30 with two tunable RF filter paths highlighted for performing Multiple Input Multiple Output (MIMO), Single Input Multiple Output (SIMO), Multiple Input Single Output (MISO), and Single Input Single Output (SISO) operations.

FIG. 33 illustrates another embodiment of a tunable RF filter structure with amplifier stages electrically connected within and between tunable RF filter paths.

FIG. 34 illustrates an embodiment of a tunable RF filter structure integrated into an integrated circuit (IC) package with multiple and separate semiconductor dies.

FIG. 35 illustrates an embodiment of the same tunable RF filter structure shown in FIG. 34, but now integrated into an IC package with a single semiconductor die.

FIG. 36 illustrates one embodiment of a tunable RF filter structure having resonators and cross-coupling capacitive structures electrically connected between the resonators so as to form a three-dimensional matrix of the resonators.

FIG. 37 shows the RF communications circuitry according to one embodiment of the RF communications circuitry.

FIG. 38 shows the RF communications circuitry according to an alternate embodiment of the RF communications circuitry.

FIG. 39 shows the RF communications circuitry according to an additional embodiment of the RF communications circuitry.

FIG. 40A is a graph illustrating a profile of an RF communications band of interest according to one embodiment of the RF communications band.

FIG. 40B is a graph illustrating a first bandpass filter response of the first tunable RF receive filter shown in FIG. 38 according to one embodiment of the first tunable RF receive filter.

FIG. 41A is a graph illustrating the first bandpass filter response and a second bandpass filter response of the first tunable RF receive filter shown in FIG. 38 according to one embodiment of the first tunable RF receive filter.

FIG. 41B is a graph illustrating the first bandpass filter response and a third bandpass filter response of the first tunable RF receive filter shown in FIG. 38 according to one embodiment of the first tunable RF receive filter.

FIG. 42 shows the RF communications circuitry according to one embodiment of the RF communications circuitry.

FIG. 43 shows the RF communications circuitry according to an alternate embodiment of the RF communications circuitry.

FIG. 44 shows the RF communications circuitry according to an additional embodiment of the RF communications circuitry.

FIG. 45 shows the RF communications circuitry according to another embodiment of the RF communications circuitry.

FIG. 46 shows the first RF filter structure shown in FIG. 45 according to one embodiment of the first RF filter structure.

FIG. 47 shows the first RF filter structure shown in FIG. 45 according to an alternate embodiment of the first RF filter structure.

FIG. 48 shows the first RF filter structure shown in FIG. 45 according to an additional embodiment of the first RF filter structure.

FIG. 49 shows the first RF filter structure shown in FIG. 45 according to another embodiment of the first RF filter structure.

FIG. 50 shows one embodiment of the RF communications circuitry and alternate RF communications circuitry.

FIG. 51 shows an electronics apparatus according to one embodiment of the electronics apparatus.

FIG. 52 shows the electronics apparatus according to an alternate embodiment of the electronics apparatus.

FIGS. 53A, 53B, and 53C are graphs illustrating relationships between an input signal and a linear capacitance, the input signal and a first nonlinear capacitance, and the input signal and a first compensation capacitance, respectively.

FIG. 54 shows the electronics apparatus according to one embodiment of the electronics apparatus.

FIG. 55A shows the electronics apparatus according to an alternate embodiment of the electronics apparatus.

FIG. 55B shows the electronics apparatus according to an additional embodiment of the electronics apparatus.

5

FIG. 56 shows the electronics apparatus according to one embodiment of the electronics apparatus.

FIG. 57 shows the electronics apparatus according to an alternate embodiment of the electronics apparatus.

FIG. 58 shows the electronics apparatus according to an additional embodiment of the electronics apparatus.

FIG. 59 shows the electronics apparatus according to one embodiment of the electronics apparatus.

FIG. 60 shows the electronics apparatus according to an alternate embodiment of the electronics apparatus.

FIG. 61 shows the electronics apparatus according to an additional embodiment of the electronics apparatus.

FIG. 62 shows the electronics apparatus according to another embodiment of the electronics apparatus.

FIG. 63 shows the electronics apparatus according to a further embodiment of the electronics apparatus.

FIG. 64 shows a first nonlinear capacitance compensation circuit illustrated in FIG. 52 according to one embodiment of the first nonlinear capacitance compensation circuit.

FIG. 65 shows the electronics apparatus according to one embodiment of the electronics apparatus.

FIG. 66 shows the electronics apparatus according to an alternate embodiment of the electronics apparatus.

FIG. 67 shows the electronics apparatus according to an additional embodiment of the electronics apparatus.

FIG. 68 shows the electronics apparatus according to another embodiment of the electronics apparatus.

FIG. 69 shows the electronics apparatus according to a further embodiment of the electronics apparatus.

FIG. 70 shows the electronics apparatus according to one embodiment of the electronics apparatus.

FIGS. 71A, 71B, 71C, and 71D are graphs illustrating linearity responses of a first nonlinear capacitance, a first compensation capacitance, a first elementary response of a first nonlinear capacitance compensation circuit, and a second elementary response of the first nonlinear capacitance compensation circuit, respectively, shown in FIG. 51.

#### DETAILED DESCRIPTION

The embodiments set forth below represent the necessary information to enable those skilled in the art to practice the disclosure and illustrate the best mode of practicing the disclosure. Upon reading the following description in light of the accompanying drawings, those skilled in the art will understand the concepts of the disclosure and will recognize applications of these concepts not particularly addressed herein. It should be understood that these concepts and applications fall within the scope of the disclosure and the accompanying claims. RF communications circuitry, which includes a first RF filter structure, is disclosed according to a first embodiment of the present disclosure. The first RF filter structure includes a first tunable RF filter path and a second tunable RF filter path. The first tunable RF filter path includes a pair of weakly coupled resonators. Additionally, a first filter parameter of the first tunable RF filter path is tuned based on a first filter control signal. A first filter parameter of the second tunable RF filter path is tuned based on a second filter control signal.

In one embodiment of the first RF filter structure, the first tunable RF filter path is directly coupled between a first common connection node and a first connection node. The second tunable RF filter path is directly coupled between a second connection node and the first common connection node.

In one embodiment of the RF communications system, the first tunable RF filter path and the second tunable RF

6

filter path do not significantly load one another at frequencies of interest. As such, by directly coupling the first tunable RF filter path and the second tunable RF filter path to the first common connection node; front-end RF switching elements may be avoided, thereby reducing cost, size, and non-linearity; and increasing efficiency and flexibility of the RF communications system. In one embodiment of the RF communications system, the first common connection node is coupled to an antenna.

Embodiments of the RF communications system include frequency division duplex (FDD) applications, time division duplex (TDD) applications, carrier-aggregation (CA) applications, multiple antenna applications, MIMO applications, hybrid applications, applications supporting multiple communications bands, the like, or any combination thereof.

FIG. 1 shows traditional communications circuitry 10 according to the prior art. The traditional communications circuitry 10 illustrated in FIG. 1 is a time-division duplex (TDD) system, which is capable of transmitting and receiving RF signals, but not simultaneously. Such a system may also be called a half-duplex system. Additionally, the traditional communications circuitry 10 may be used as a simplex system, which is a system that only transmits RF signals or only receives RF signals. Traditional communications systems often use fixed frequency filters. As a result, to cover multiple communications bands, switching elements are needed to select between different signal paths.

The traditional communications circuitry 10 includes traditional RF system control circuitry 12, traditional RF front-end circuitry 14, and a first RF antenna 16. The traditional RF front-end circuitry 14 includes traditional RF front-end control circuitry 18, first traditional antenna matching circuitry 20, first traditional RF receive circuitry 22, first traditional RF transmit circuitry 24, a first traditional RF switch 26, and a second traditional RF switch 28. The first traditional RF switch 26 is coupled between the first traditional antenna matching circuitry 20 and the first traditional RF receive circuitry 22. The second traditional RF switch 28 is coupled between the first traditional antenna matching circuitry 20 and the first traditional RF transmit circuitry 24. The first RF antenna 16 is coupled to the first traditional antenna matching circuitry 20. The first traditional antenna matching circuitry 20 provides at least partial impedance matching between the first RF antenna 16 and either the first traditional RF receive circuitry 22 or the first traditional RF transmit circuitry 24.

The traditional RF system control circuitry 12 provides the necessary control functions needed to facilitate RF communications between the traditional communications circuitry 10 and other RF devices. The traditional RF system control circuitry 12 processes baseband signals needed for the RF communications. As such, the traditional RF system control circuitry 12 provides a first traditional upstream transmit signal TUT1 to the first traditional RF transmit circuitry 24. The first traditional upstream transmit signal TUT1 may be a baseband transmit signal, an intermediate frequency (IF) transmit signal, or an RF transmit signal. Conversely, the traditional RF system control circuitry 12 receives a first traditional downstream receive signal TDR1 from the first traditional RF receive circuitry 22. The first traditional downstream receive signal TDR1 may be a baseband receive signal, an IF receive signal, or an RF receive signal.

The first traditional RF transmit circuitry 24 may include up-conversion circuitry, amplification circuitry, power supply circuitry, filtering circuitry, switching circuitry, combining circuitry, splitting circuitry, dividing circuitry, clocking

circuitry, the like, or any combination thereof. Similarly, the first traditional RF receive circuitry 22 may include down-conversion circuitry, amplification circuitry, power supply circuitry, filtering circuitry, switching circuitry, combining circuitry, splitting circuitry, dividing circuitry, clocking circuitry, the like, or any combination thereof.

The traditional RF system control circuitry 12 provides a traditional front-end control signal TFEC to the traditional RF front-end control circuitry 18. The traditional RF front-end control circuitry 18 provides a first traditional switch control signal TCS1 and a second traditional switch control signal TCS2 to the first traditional RF switch 26 and the second traditional RF switch 28, respectively, based on the traditional front-end control signal TFEC. As such, the traditional RF system control circuitry 12 controls the first traditional RF switch 26 and the second traditional RF switch 28 via the traditional front-end control signal TFEC. The first traditional RF switch 26 is in one of an ON state and an OFF state based on the first traditional switch control signal TCS1. The second traditional RF switch 28 is in one of an ON state and an OFF state based on the second traditional switch control signal TCS2.

Half-duplex operation of the traditional communications circuitry 10 is accomplished using the first traditional RF switch 26 and the second traditional RF switch 28. When the traditional communications circuitry 10 is transmitting RF signals via the first RF antenna 16, the first traditional RF switch 26 is in the OFF state and the second traditional RF switch 28 is in the ON state. As such, the first traditional antenna matching circuitry 20 is electrically isolated from the first traditional RF receive circuitry 22 and the first traditional antenna matching circuitry 20 is electrically coupled to the first traditional RF transmit circuitry 24. In this regard, the traditional RF system control circuitry 12 provides the first traditional upstream transmit signal TUT1 to the first traditional RF transmit circuitry 24, which provides a traditional transmit signal TTX to the first RF antenna 16 via the second traditional RF switch 28 and the first traditional antenna matching circuitry 20 based on the first traditional upstream transmit signal TUT1.

When the traditional communications circuitry 10 is receiving RF signals via the first RF antenna 16, the first traditional RF switch 26 is in the ON state and the second traditional RF switch 28 is in the OFF state. As such, the first traditional antenna matching circuitry 20 is isolated from the first traditional RF transmit circuitry 24 and the first traditional antenna matching circuitry 20 is electrically coupled to the first traditional RF receive circuitry 22. In this regard, the first traditional antenna matching circuitry 20 receives the RF signals from the first RF antenna 16 and forwards the RF signals via the first traditional RF switch 26 to the first traditional RF receive circuitry 22. The first traditional RF switch 26 provides a traditional receive signal TRX to the first traditional RF receive circuitry 22, which provides a first traditional downstream receive signal TDR1 to the traditional RF system control circuitry 12 based on the traditional receive signal TRX.

Since the traditional communications circuitry 10 illustrated in FIG. 1 is a half-duplex system, during operation, the first traditional RF switch 26 and the second traditional RF switch 28 are not simultaneously in the ON state. Therefore, the first traditional RF receive circuitry 22 and the first traditional RF transmit circuitry 24 are isolated from one another. As such, the first traditional RF receive circuitry 22 and the first traditional RF transmit circuitry 24 are prevented from interfering with one another.

FIG. 2 shows the traditional communications circuitry 10 according to the prior art. The traditional communications circuitry 10 illustrated in FIG. 2 is similar to the traditional communications circuitry 10 illustrated in FIG. 1, except in the traditional communications circuitry 10 illustrated in FIG. 2, the traditional RF front-end control circuitry 18, the first traditional RF switch 26, and the second traditional RF switch 28 are omitted, and the traditional RF front-end control circuitry 14 further includes a first traditional RF duplexer 30. The first traditional RF duplexer 30 is coupled between the first traditional antenna matching circuitry 20 and the first traditional RF receive circuitry 22, and is further coupled between the first traditional antenna matching circuitry 20 and the first traditional RF transmit circuitry 24.

The traditional communications circuitry 10 illustrated in FIG. 2 may be used as a TDD system or a simplex system. However, the traditional communications circuitry 10 illustrated in FIG. 2 may also be used as a frequency-division duplex (FDD) system, which is capable of transmitting and receiving RF signals simultaneously. Such a system may also be called a full-duplex system.

When the traditional communications circuitry 10 is transmitting RF signals via the first RF antenna 16, the traditional RF system control circuitry 12 provides the first traditional upstream transmit signal TUT1 to the first traditional RF transmit circuitry 24, which provides the traditional transmit signal TTX to the first RF antenna 16 via first traditional RF duplexer 30 based on the first traditional upstream transmit signal TUT1.

When the traditional communications circuitry 10 is receiving RF signals via the first RF antenna 16, the first traditional antenna matching circuitry 20 receives the RF signals from the first RF antenna 16 and forwards the RF signals via the first traditional RF duplexer 30 to the first traditional RF receive circuitry 22. As such, the first traditional RF duplexer 30 provides the traditional receive signal TRX to the first traditional RF receive circuitry 22, which provides the first traditional downstream receive signal TDR1 to the traditional RF system control circuitry 12 based on the traditional receive signal TRX.

The first traditional RF duplexer 30 provides filtering, such that the first traditional RF receive circuitry 22 and the first traditional RF transmit circuitry 24 are substantially isolated from one another. As such, the first traditional RF receive circuitry 22 and the first traditional RF transmit circuitry 24 are prevented from interfering with one another. Traditional FDD systems using duplexers with high rejection ratios have a fixed frequency transfer. Covering multiple communications bands requires multiple duplexers and switches to route RF signals through appropriate signal paths.

FIG. 3 shows the traditional communications circuitry 10 according to the prior art. The traditional communications circuitry 10 illustrated in FIG. 3 is a carrier aggregation (CA) based system, which is capable of transmitting or receiving multiple simultaneous transmit signals or multiple simultaneous receive signals, respectively, or both. Each of the simultaneous transmit signals is in a frequency band that is different from each frequency band of a balance of the simultaneous transmit signals. Similarly, each of the simultaneous receive signals is in a frequency band that is different from each frequency band of a balance of the simultaneous receive signals. The traditional communications circuitry 10 may operate as a simplex system, a half-duplex system, or a full-duplex system.

The traditional communications circuitry 10 includes the traditional RF system control circuitry 12, the traditional RF

front-end circuitry 14, the first RF antenna 16, and a second RF antenna 32. The traditional RF front-end circuitry 14 includes the first traditional antenna matching circuitry 20, the first traditional RF receive circuitry 22, the first traditional RF transmit circuitry 24, the first traditional RF duplexer 30, first traditional antenna switching circuitry 34, a second traditional RF duplexer 36, a third traditional RF duplexer 38, second traditional antenna matching circuitry 40, second traditional antenna switching circuitry 42, a fourth traditional RF duplexer 44, a fifth traditional RF duplexer 46, a sixth traditional RF duplexer 48, second traditional RF receive circuitry 50, and second traditional RF transmit circuitry 52. Traditional CA systems use fixed frequency filters and diplexers, triplexers, or both to combine signal paths, which increases complexity. Alternatively, additional switch paths may be used, but may degrade performance.

The first traditional antenna matching circuitry 20 is coupled between the first RF antenna 16 and the first traditional antenna switching circuitry 34. The second traditional antenna matching circuitry 40 is coupled between the second RF antenna 32 and the second traditional antenna switching circuitry 42. The first traditional RF duplexer 30 is coupled between the first traditional antenna switching circuitry 34 and the first traditional RF receive circuitry 22, and is further coupled between the first traditional antenna switching circuitry 34 and the first traditional RF transmit circuitry 24. The second traditional RF duplexer 36 is coupled between the first traditional antenna switching circuitry 34 and the first traditional RF receive circuitry 22, and is further coupled between the first traditional antenna switching circuitry 34 and the first traditional RF transmit circuitry 24. The third traditional RF duplexer 38 is coupled between the first traditional antenna switching circuitry 34 and the first traditional RF receive circuitry 22, and is further coupled between the first traditional antenna switching circuitry 34 and the first traditional RF transmit circuitry 24.

The fourth traditional RF duplexer 44 is coupled between the second traditional antenna switching circuitry 42 and the second traditional RF receive circuitry 50, and is further coupled between the second traditional antenna switching circuitry 42 and the second traditional RF transmit circuitry 52. The fifth traditional RF duplexer 46 is coupled between the second traditional antenna switching circuitry 42 and the second traditional RF receive circuitry 50, and is further coupled between the second traditional antenna switching circuitry 42 and the second traditional RF transmit circuitry 52. The sixth traditional RF duplexer 48 is coupled between the second traditional antenna switching circuitry 42 and the second traditional RF receive circuitry 50, and is further coupled between the second traditional antenna switching circuitry 42 and the second traditional RF transmit circuitry 52.

The first traditional RF duplexer 30 is associated with a first aggregated receive band, a first aggregated transmit band, or both. The second traditional RF duplexer 36 is associated with a second aggregated receive band, a second aggregated transmit band, or both. The third traditional RF duplexer 38 is associated with a third aggregated receive band, a third aggregated transmit band, or both. The fourth traditional RF duplexer 44 is associated with a fourth aggregated receive band, a fourth aggregated transmit band, or both. The fifth traditional RF duplexer 46 is associated with a fifth aggregated receive band, a fifth aggregated transmit band, or both. The sixth traditional RF duplexer 48 is associated with a sixth aggregated receive band, a sixth aggregated transmit band, or both.

The first traditional antenna switching circuitry 34 couples a selected one of the first traditional RF duplexer 30, the second traditional RF duplexer 36, and the third traditional RF duplexer 38 to the first traditional antenna matching circuitry 20. Therefore, the first RF antenna 16 is associated with a selected one of the first aggregated receive band, the second aggregated receive band, and the third aggregated receive band; with a selected one of the first aggregated transmit band, the second aggregated transmit band, and the third aggregated transmit band; or both.

Similarly, the second traditional antenna switching circuitry 42 couples a selected one of the fourth traditional RF duplexer 44, the fifth traditional RF duplexer 46, and the sixth traditional RF duplexer 48 to the second traditional antenna matching circuitry 40. Therefore, the second RF antenna 32 is associated with a selected one of the fourth aggregated receive band, the fifth aggregated receive band, and the sixth aggregated receive band; with a selected one of the fourth aggregated transmit band, the fifth aggregated transmit band, and the sixth aggregated transmit band; or both.

During transmit CA, the traditional RF system control circuitry 12 provides the first traditional upstream transmit signal TUT1 to the first traditional RF transmit circuitry 24, which forwards the first traditional upstream transmit signal TUT1 to the first RF antenna 16 for transmission via the selected one of the first traditional RF duplexer 30, the second traditional RF duplexer 36, and the third traditional RF duplexer 38; via the first traditional antenna switching circuitry 34; and via the first traditional antenna matching circuitry 20.

Additionally, during transmit CA, the traditional RF system control circuitry 12 provides a second traditional upstream transmit signal TUT2 to the second traditional RF transmit circuitry 52, which forwards the second traditional upstream transmit signal TUT2 to the second RF antenna 32 for transmission via the selected one of the fourth traditional RF duplexer 44, the fifth traditional RF duplexer 46, and the sixth traditional RF duplexer 48; via the second traditional antenna switching circuitry 42; and via the second traditional antenna matching circuitry 40.

During receive CA, the first RF antenna 16 forwards a received RF signal to the first traditional RF receive circuitry 22 via the first traditional antenna matching circuitry 20, the first traditional antenna switching circuitry 34, and the selected one of the first traditional RF duplexer 30, the second traditional RF duplexer 36, and the third traditional RF duplexer 38. The first traditional RF receive circuitry 22 provides the first traditional downstream receive signal TDR1 to the traditional RF system control circuitry 12 based on the received RF signal.

Additionally, during receive CA, the second RF antenna 32 forwards a received RF signal to the second traditional RF receive circuitry 50 via the second traditional antenna matching circuitry 40, the second traditional antenna switching circuitry 42, and the selected one of the fourth traditional RF duplexer 44, the fifth traditional RF duplexer 46, and the sixth traditional RF duplexer 48. The second traditional RF receive circuitry 50 provides a second traditional downstream receive signal TDR2 to the traditional RF system control circuitry 12 based on the received RF signal.

Since only the selected one of the first traditional RF duplexer 30, the second traditional RF duplexer 36, and the third traditional RF duplexer 38 is coupled to the first traditional antenna matching circuitry 20; the first traditional antenna switching circuitry 34 isolates each of the first traditional RF duplexer 30, the second traditional RF

11

duplexer 36, and the third traditional RF duplexer 38 from one another; and prevents each of the first traditional RF duplexer 30, the second traditional RF duplexer 36, and the third traditional RF duplexer 38 from interfering with one another.

Similarly, since only the selected one of the fourth traditional RF duplexer 44, the fifth traditional RF duplexer 46, and the sixth traditional RF duplexer 48 is coupled to the second traditional antenna matching circuitry 40; the second traditional antenna matching circuitry 40 isolates each of the fourth traditional RF duplexer 44, the fifth traditional RF duplexer 46, and the sixth traditional RF duplexer 48 from one another; and prevents each of the fourth traditional RF duplexer 44, the fifth traditional RF duplexer 46, and the sixth traditional RF duplexer 48 from interfering with one another.

FIG. 4 shows RF communications circuitry 54 according to one embodiment of the RF communications circuitry 54. The RF communications circuitry 54 includes RF system control circuitry 56, RF front-end circuitry 58, and the first RF antenna 16. The RF front-end circuitry 58 includes a first RF filter structure 60, RF receive circuitry 62, and RF transmit circuitry 64. The first RF filter structure 60 includes a first tunable RF filter path 66 and a second tunable RF filter path 68. Additionally, the first RF filter structure 60 has a first connection node 70, a second connection node 72, and a first common connection node 74. In one embodiment of the RF system control circuitry 56, the RF system control circuitry 56 is an RF transceiver. In one embodiment of the first tunable RF filter path 66, the first tunable RF filter path 66 includes a pair of weakly coupled resonators R(1,1), R(1,2) (FIG. 22). As such, in one embodiment of the first RF filter structure 60, the RF filter structure 60 includes the pair of weakly coupled resonators R(1,1), R(1,2) (FIG. 21).

In alternate embodiments of the first RF filter structure 60, any or all of the first connection node 70, the second connection node 72, and the first common connection node 74 are external to the first RF filter structure 60. In one embodiment of the first tunable RF filter path 66, the first tunable RF filter path 66 includes a first pair (not shown) of weakly coupled resonators. In one embodiment of the second tunable RF filter path 68, the second tunable RF filter path 68 includes a second pair (not shown) of weakly coupled resonators.

In one embodiment of the first RF filter structure 60, the first tunable RF filter path 66 is directly coupled between the first common connection node 74 and the first connection node 70, the second tunable RF filter path 68 is directly coupled between the second connection node 72 and the first common connection node 74, and the first RF antenna 16 is directly coupled to the first common connection node 74. In another embodiment of the RF communications circuitry 54, the first RF antenna 16 is omitted. Additionally, the RF receive circuitry 62 is coupled between the first connection node 70 and the RF system control circuitry 56, and the RF transmit circuitry 64 is coupled between the second connection node 72 and the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66 is a first RF receive filter, such that the first RF antenna 16 forwards a received RF signal via the first common connection node 74 to provide a first upstream RF receive signal RU1 to the first tunable RF filter path 66, which receives and filters the first upstream RF receive signal RU1 to provide a first filtered RF receive signal RF1 to the RF receive circuitry 62. The RF receive circuitry 62 may include down-conversion circuitry, amplification circuitry, power supply circuitry, filtering cir-

12

cuitry, switching circuitry, combining circuitry, splitting circuitry, dividing circuitry, clocking circuitry, the like, or any combination thereof. The RF receive circuitry 62 processes the first filtered RF receive signal RF1 to provide a first receive signal RX1 to the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the second tunable RF filter path 68 is a first RF transmit filter, such that the RF system control circuitry 56 provides a first transmit signal TX1 to the RF transmit circuitry 64, which processes the first transmit signal TX1 to provide a first upstream RF transmit signal TU1 to the second tunable RF filter path 68. The RF transmit circuitry 64 may include up-conversion circuitry, amplification circuitry, power supply circuitry, filtering circuitry, switching circuitry, combining circuitry, splitting circuitry, dividing circuitry, clocking circuitry, the like, or any combination thereof. The second tunable RF filter path 68 receives and filters the first upstream RF transmit signal TU1 to provide a first filtered RF transmit signal TF1, which is transmitted via the first common connection node 74 by the first RF antenna 16.

The RF system control circuitry 56 provides a first filter control signal FCS1 to the first tunable RF filter path 66 and provides a second filter control signal FCS2 to the second tunable RF filter path 68. As such, in one embodiment of the RF communications circuitry 54, the RF system control circuitry 56 tunes a first filter parameter of the first tunable RF filter path 66 using the first filter control signal FCS1. Additionally, the RF system control circuitry 56 tunes a first filter parameter of the second tunable RF filter path 68 using the second filter control signal FCS2.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66 and the second tunable RF filter path 68 do not significantly load one another at frequencies of interest. As such, by directly coupling the first tunable RF filter path 66 and the second tunable RF filter path 68 to the first common connection node 74; front-end RF switching elements may be avoided, thereby reducing cost, size, and non-linearity; and increasing efficiency and flexibility of the RF communications circuitry 54. Since tunable RF filters can support multiple communications bands using a single signal path, they can simplify front-end architectures by eliminating switching and duplexing components.

In one embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is used as an FDD communications system, such that the first upstream RF receive signal RU1 and the first filtered RF transmit signal TF1 are full-duplex signals. In an alternate embodiments of the RF communications circuitry 54, the RF communications circuitry 54 is used as a TDD communications system, such that the first upstream RF receive signal RU1 and the first filtered RF transmit signal TF1 are half-duplex signals. In additional embodiments of the RF communications circuitry 54, the RF communications circuitry 54 is used as a simplex communications system, such that the first upstream RF receive signal RU1 is a simplex signal and the first filtered RF transmit signal TF1 is not present. In other embodiments of the RF communications circuitry 54, the RF communications circuitry 54 is used as a simplex communications system, such that the first upstream RF receive signal RU1 is not present and the first filtered RF transmit signal TF1 is a simplex signal.

FIG. 5 is a graph illustrating filtering characteristics of the first tunable RF filter path 66 and the second tunable RF filter path 68 illustrated in FIG. 4 according to one embodiment of the first tunable RF filter path 66 and the second

13

tunable RF filter path 68. The first tunable RF filter path 66 is a first RF bandpass filter, which functions as the first RF receive filter, and the second tunable RF filter path 68 is a second RF bandpass filter, which functions as the first RF transmit filter. A bandwidth 76 of the first RF bandpass filter, a center frequency 78 of the first RF bandpass filter, a bandwidth 80 of the second RF bandpass filter, a center frequency 82 of the second RF bandpass filter, a frequency 84 of the first upstream RF receive signal RU1 (FIG. 4), and a frequency 86 of the first filtered RF transmit signal TF1 (FIG. 4) are shown. Operation of the first RF bandpass filter and the second RF bandpass filter is such that the first RF bandpass filter and the second RF bandpass filter do not significantly interfere with one another. In this regard, the bandwidth 76 of the first RF bandpass filter does not overlap the bandwidth 80 of the second RF bandpass filter.

In one embodiment of the first RF receive filter and the first RF transmit filter, the first RF receive filter and the first RF transmit filter in combination function as an RF duplexer. As such, a duplex frequency 88 of the RF duplexer is about equal to a difference between the frequency 84 of the first upstream RF receive signal RU1 (FIG. 4) and the frequency 86 of the first filtered RF transmit signal TF1 (FIG. 4).

In one embodiment of the first tunable RF filter path 66, the first filter parameter of the first tunable RF filter path 66 is tunable based on the first filter control signal FCS1. In an alternate embodiment of the first tunable RF filter path 66, both the first filter parameter of the first tunable RF filter path 66 and a second filter parameter of the first tunable RF filter path 66 are tunable based on the first filter control signal FCS1. Similarly, in one embodiment of the second tunable RF filter path 68, the first filter parameter of the second tunable RF filter path 68 is tunable based on the second filter control signal FCS2. In an alternate embodiment of the second tunable RF filter path 68, both the first filter parameter of the second tunable RF filter path 68 and a second filter parameter of the second tunable RF filter path 68 are tunable based on the second filter control signal FCS2.

The first filter parameter of the first tunable RF filter path 66 is the center frequency 78 of the first RF bandpass filter. The second filter parameter of the first tunable RF filter path 66 is the bandwidth 76 of the first RF bandpass filter. The first filter parameter of the second tunable RF filter path 68 is the center frequency 82 of the second RF bandpass filter. The second filter parameter of the second tunable RF filter path 68 is the bandwidth 80 of the second RF bandpass filter.

FIGS. 6A and 6B are graphs illustrating filtering characteristics of the first tunable RF filter path 66 and the second tunable RF filter path 68, respectively, illustrated in FIG. 4 according to an alternate embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, respectively. The first tunable RF filter path 66 is an RF lowpass filter and the second tunable RF filter path 68 is an RF highpass filter. FIG. 6A shows a frequency response curve 90 of the RF lowpass filter and FIG. 6B shows a frequency response curve 92 of the RF highpass filter. Additionally FIG. 6A shows a break frequency 94 of the RF lowpass filter and FIG. 6B shows a break frequency 96 of the RF highpass filter. Both FIGS. 6A and 6B show the frequency 84 of the first upstream RF receive signal RU1 (FIG. 4), the frequency 86 of the first filtered RF transmit signal TF1 (FIG. 4), and the duplex frequency 88 of the RF duplexer for clarification. However, the RF lowpass filter and the RF highpass filter in combination function as an RF duplexer. The first filter parameter of the first tunable RF filter path 66 is the break frequency 94 of the RF lowpass

14

filter. In one embodiment of the RF lowpass filter, the RF lowpass filter has bandpass filter characteristics. The first filter parameter of the second tunable RF filter path 68 is the break frequency 96 of the RF highpass filter. In one embodiment of the RF highpass filter, the RF highpass filter has bandpass filter characteristics. In one embodiment of the RF duplexer, the break frequency 96 of the RF highpass filter is about equal to the break frequency 94 of the RF lowpass filter.

FIG. 7 shows the RF communications circuitry 54 according to one embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 7 is similar to the RF communications circuitry 54 illustrated in FIG. 4, except in the RF front-end circuitry 58 illustrated in FIG. 7, the RF transmit circuitry 64 (FIG. 4) is omitted and the RF front-end circuitry 58 further includes RF front-end control circuitry 98.

The RF system control circuitry 56 provides a front-end control signal FEC to the RF front-end control circuitry 98. The RF front-end control circuitry 98 provides the first filter control signal FCS1 and the second filter control signal FCS2 based on the front-end control signal FEC. In the RF communications circuitry 54 illustrated in FIG. 4, the RF system control circuitry 56 provides the first filter control signal FCS1 and the second filter control signal FCS2 directly. In general, the RF communications circuitry 54 includes control circuitry, which may be either the RF system control circuitry 56 or the RF front-end control circuitry 98, that provides the first filter control signal FCS1 and the second filter control signal FCS2. As such, in one embodiment of the RF communications circuitry 54, the control circuitry tunes a first filter parameter of the first tunable RF filter path 66 using the first filter control signal FCS1. Additionally, the control circuitry tunes a first filter parameter of the second tunable RF filter path 68 using the second filter control signal FCS2. In an additional embodiment of the RF communications circuitry 54, the control circuitry further tunes a second filter parameter of the first tunable RF filter path 66 using the first filter control signal FCS1; and the control circuitry further tunes a second filter parameter of the second tunable RF filter path 68 using the second filter control signal FCS2.

In alternate embodiments of the first RF filter structure 60, any or all of the first connection node 70, the second connection node 72, and the first common connection node 74 are external to the first RF filter structure 60. In one embodiment of the first tunable RF filter path 66, the first tunable RF filter path 66 includes a first pair (not shown) of weakly coupled resonators. In one embodiment of the second tunable RF filter path 68, the second tunable RF filter path 68 includes a second pair (not shown) of weakly coupled resonators.

In one embodiment of the first RF filter structure 60, the first tunable RF filter path 66 is directly coupled between the first common connection node 74 and the first connection node 70, the second tunable RF filter path 68 is directly coupled between the second connection node 72 and the first common connection node 74, and the first RF antenna 16 is directly coupled to the first common connection node 74. In another embodiment of the RF communications circuitry 54, the first RF antenna 16 is omitted. Additionally, the RF receive circuitry 62 is coupled between the first connection node 70 and the RF system control circuitry 56, and the RF receive circuitry 62 is further coupled between the second connection node 72 and the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66 is a first RF receive

15

filter, such that the first RF antenna 16 forwards a first received RF signal via the first common connection node 74 to provide a first upstream RF receive signal RU1 to the first tunable RF filter path 66, which receives and filters the first upstream RF receive signal RU1 to provide a first filtered RF receive signal RF1 to the RF receive circuitry 62. Additionally, the second tunable RF filter path 68 is a second RF receive filter, such that the first RF antenna 16 forwards a second received RF signal via the first common connection node 74 to provide a second upstream RF receive signal RU2 to the second tunable RF filter path 68, which receives and filters the second upstream RF receive signal RU2 to provide a second filtered RF receive signal RF2 to the RF receive circuitry 62.

The RF receive circuitry 62 may include down-conversion circuitry, amplification circuitry, power supply circuitry, filtering circuitry, switching circuitry, combining circuitry, splitting circuitry, dividing circuitry, clocking circuitry, the like, or any combination thereof. The RF receive circuitry 62 processes the first filtered RF receive signal RF1 to provide a first receive signal RX1 to the RF system control circuitry 56. Additionally, the RF receive circuitry 62 processes the second filtered RF receive signal RF2 to provide a second receive signal RX2 to the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66 and the second tunable RF filter path 68 do not significantly load one another at frequencies of interest. As such, by directly coupling the first tunable RF filter path 66 and the second tunable RF filter path 68 to the first common connection node 74, front-end RF switching elements may be avoided, thereby reducing cost, size, and non-linearity; and increasing efficiency and flexibility of the RF communications circuitry 54.

In this regard, in one embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, each of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a bandpass filter having a unique center frequency. As such, the first filter parameter of each of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a unique center frequency.

In an alternate embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a lowpass filter, and another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a highpass filter. As such, the first filter parameter of each of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a break frequency.

In an additional embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a lowpass filter, and another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a bandpass filter. As such, the first filter parameter of one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a center frequency, and the first filter parameter of another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a break frequency.

In an additional embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a highpass filter, and another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a bandpass filter. As such, the first filter parameter of one of the first tunable RF filter path 66 and the second

16

tunable RF filter path 68 is a center frequency, and the first filter parameter of another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a break frequency.

In one embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is a receive only CA system, such that the first tunable RF filter path 66, which is the first RF receive filter, and the second tunable RF filter path 68, which is the second RF receive filter, simultaneously receive and filter the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2, respectively, via the first common connection node 74. As such, the first RF filter structure 60 functions as a demultiplexer. In this regard, each of the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2 has a unique carrier frequency. Using receive CA may increase an effective receive bandwidth of the RF communications circuitry 54.

In another embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is a receive only communications system, such that the first tunable RF filter path 66, which is the first RF receive filter, and the second tunable RF filter path 68, which is the second RF receive filter, do not simultaneously receive and filter the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2, respectively. As such, the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2 are nonsimultaneous signals. Each of the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2 may be associated with a unique RF communications band.

FIG. 8 shows the RF communications circuitry 54 according to an alternate embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 8 is similar to the RF communications circuitry 54 illustrated in FIG. 7, except in the RF front-end circuitry 58 illustrated in FIG. 8, the RF receive circuitry 62 is omitted and the RF transmit circuitry 64 is included.

The RF system control circuitry 56 provides the front-end control signal FEC to the RF front-end control circuitry 98. The RF front-end control circuitry 98 provides the first filter control signal FCS1 and the second filter control signal FCS2 based on the front-end control signal FEC. In the RF communications circuitry 54 illustrated in FIG. 4, the RF system control circuitry 56 provides the first filter control signal FCS1 and the second filter control signal FCS2 directly. In general, the RF communications circuitry 54 includes control circuitry, which may be either the RF system control circuitry 56 or the RF front-end control circuitry 98, that provides the first filter control signal FCS1 and the second filter control signal FCS2. As such, in one embodiment of the RF communications circuitry 54, the control circuitry tunes a first filter parameter of the first tunable RF filter path 66 using the first filter control signal FCS1. Additionally, the control circuitry tunes a first filter parameter of the second tunable RF filter path 68 using the second filter control signal FCS2. In an additional embodiment of the RF communications circuitry 54, the control circuitry further tunes a second filter parameter of the first tunable RF filter path 66 using the first filter control signal FCS1; and the control circuitry further tunes a second filter parameter of the second tunable RF filter path 68 using the second filter control signal FCS2.

In alternate embodiments of the first RF filter structure 60, any or all of the first connection node 70, the second connection node 72, and the first common connection node 74 are external to the first RF filter structure 60. In one

17

embodiment of the first tunable RF filter path 66, the first tunable RF filter path 66 includes a first pair (not shown) of weakly coupled resonators. In one embodiment of the second tunable RF filter path 68, the second tunable RF filter path 68 includes a second pair (not shown) of weakly coupled resonators.

In one embodiment of the first RF filter structure 60, the first tunable RF filter path 66 is directly coupled between the first common connection node 74 and the first connection node 70, the second tunable RF filter path 68 is directly coupled between the second connection node 72 and the first common connection node 74, and the first RF antenna 16 is directly coupled to the first common connection node 74. In another embodiment of the RF communications circuitry 54, the first RF antenna 16 is omitted. Additionally, the RF transmit circuitry 64 is coupled between the first connection node 70 and the RF system control circuitry 56, and the RF transmit circuitry 64 is further coupled between the second connection node 72 and the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66 is a first RF transmit filter, such that the RF system control circuitry 56 provides the first transmit signal TX1 to the RF transmit circuitry 64, which processes the first transmit signal TX1 to provide a first upstream RF transmit signal TU1 to the first tunable RF filter path 66. Similarly, the second tunable RF filter path 68 is a second RF transmit filter, such that the RF system control circuitry 56 provides a second transmit signal TX2 to the RF transmit circuitry 64, which processes the second transmit signal TX2 to provide a second upstream RF transmit signal TU2 to the second tunable RF filter path 68.

The RF transmit circuitry 64 may include up-conversion circuitry, amplification circuitry, power supply circuitry, filtering circuitry, switching circuitry, combining circuitry, splitting circuitry, dividing circuitry, clocking circuitry, the like, or any combination thereof. The first tunable RF filter path 66 receives and filters the first upstream RF transmit signal TU1 to provide the first filtered RF transmit signal TF1, which is transmitted via the first common connection node 74 by the first RF antenna 16. Similarly, the second tunable RF filter path 68 receives and filters the second upstream RF transmit signal TU2 to provide a second filtered RF transmit signal TF2, which is transmitted via the first common connection node 74 by the first RF antenna 16.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66 and the second tunable RF filter path 68 do not significantly load one another at frequencies of interest. As such, by directly coupling the first tunable RF filter path 66 and the second tunable RF filter path 68 to the first common connection node 74, front-end RF switching elements may be avoided, thereby reducing cost, size, and non-linearity; and increasing efficiency and flexibility of the RF communications circuitry 54.

In this regard, in one embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, each of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a bandpass filter having a unique center frequency. As such, the first filter parameter of each of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a unique center frequency.

In an alternate embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a lowpass filter, and another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a highpass filter. As such, the first filter parameter

18

of each of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a break frequency.

In an additional embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a lowpass filter, and another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a bandpass filter. As such, the first filter parameter of one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a center frequency, and the first filter parameter of another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a break frequency.

In an additional embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a highpass filter, and another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a bandpass filter. As such, the first filter parameter of one of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a center frequency, and the first filter parameter of another of the first tunable RF filter path 66 and the second tunable RF filter path 68 is a break frequency.

In one embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is a transmit only CA system, such that the first tunable RF filter path 66, which is the first RF transmit filter, and the second tunable RF filter path 68, which is the second RF transmit filter, simultaneously receive and filter the first upstream RF transmit signal TU1 and the second upstream RF transmit signal TU2, respectively, to simultaneously provide the first filtered RF transmit signal TF1 and the second filtered RF transmit signal TF2, respectively, via the first common connection node 74. As such, the first RF filter structure 60 functions as a multiplexer. In this regard, each of the first filtered RF transmit signal TF1 and the second filtered RF transmit signal TF2 has a unique carrier frequency. Using transmit CA may increase an effective transmit bandwidth of the RF communications circuitry 54.

In another embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is a transmit only communications system, such that the first tunable RF filter path 66, which is the first RF transmit filter, and the second tunable RF filter path 68, which is the second RF transmit filter, do not simultaneously receive and filter the first upstream RF transmit signal TU1 and the second upstream RF transmit signal TU2, respectively. As such, the first filtered RF transmit signal TF1 and the second filtered RF transmit signal TF2 are nonsimultaneous signals. Each of the first filtered RF transmit signal TF1 and the second filtered RF transmit signal TF2 may be associated with a unique RF communications band.

FIGS. 9A and 9B are graphs illustrating filtering characteristics of the first tunable RF filter path 66 and the second tunable RF filter path 68, respectively, illustrated in FIG. 8 according to an additional embodiment of the first tunable RF filter path 66 and the second tunable RF filter path 68, respectively. FIG. 9A shows a frequency response curve 100 of the first tunable RF filter path 66 and FIG. 9B shows a frequency response curve 102 of the second tunable RF filter path 68. The first tunable RF filter path 66 and the second tunable RF filter path 68 are both bandpass filters having the frequency response curves 100, 102 illustrated in FIGS. 9A and 9B, respectively. In this regard, the first tunable RF filter path 66 and the second tunable RF filter path 68 can be

19

directly coupled to one another via the first common connection node 74 (FIG. 8) without interfering with one another.

FIGS. 10A and 10B are graphs illustrating filtering characteristics of the first traditional RF duplexer 30 and the second traditional RF duplexer 36, respectively, illustrated in FIG. 3 according to the prior art. FIG. 10A shows a frequency response curve 104 of the first traditional RF duplexer 30 and FIG. 10B shows a frequency response curve 106 of the second traditional RF duplexer 36. There is interference 108 between the frequency response curve 104 of the first traditional RF duplexer 30 and the frequency response curve 106 of the second traditional RF duplexer 36 as shown in FIGS. 10A and 10B. In this regard, the first traditional RF duplexer 30 and the second traditional RF duplexer 36 cannot be directly coupled to one another without interfering with one another. To avoid interference between different filters, traditional systems use RF switches to disconnect unused filters.

FIG. 11 shows the RF communications circuitry 54 according to one embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 11 is similar to the RF communications circuitry 54 illustrated in FIG. 8, except in the RF communications circuitry 54 illustrated in FIG. 11, the RF front-end circuitry 58 further includes the RF receive circuitry 62 and the first RF filter structure 60 further includes a third tunable RF filter path 110 and a fourth tunable RF filter path 112. Additionally, the RF front-end circuitry 58 has the first connection node 70, the second connection node 72, the first common connection node 74, a third connection node 114 and a fourth connection node 116, such that all of the first connection node 70, the second connection node 72, the first common connection node 74, the third connection node 114 and the fourth connection node 116 are external to the first RF filter structure 60. In an alternate of the RF front-end circuitry 58, any or all of the first connection node 70, the second connection node 72, the first common connection node 74, a third connection node 114 and a fourth connection node 116 are internal to the first RF filter structure 60.

The RF front-end control circuitry 98 further provides a third filter control signal FCS3 to the third tunable RF filter path 110 and a fourth filter control signal FCS4 to the fourth tunable RF filter path 112 based on the front-end control signal FEC. In one embodiment of the RF communications circuitry 54, the control circuitry tunes a first filter parameter of the third tunable RF filter path 110 using the third filter control signal FCS3. Additionally, the control circuitry tunes a first filter parameter of the fourth tunable RF filter path 112 using the fourth filter control signal FCS4. In an additional embodiment of the RF communications circuitry 54, the control circuitry further tunes a second filter parameter of the third tunable RF filter path 110 using the third filter control signal FCS3; and the control circuitry further tunes a second filter parameter of the fourth tunable RF filter path 112 using the fourth filter control signal FCS4.

In one embodiment of the third tunable RF filter path 110, the third tunable RF filter path 110 includes a third pair (not shown) of weakly coupled resonators. In one embodiment of the fourth tunable RF filter path 112, the fourth tunable RF filter path 112 includes a fourth pair (not shown) of weakly coupled resonators.

In one embodiment of the third tunable RF filter path 110 and the fourth tunable RF filter path 112, the third tunable RF filter path 110 is directly coupled between the first common connection node 74 and the third connection node 114, and the fourth tunable RF filter path 112 is directly

20

coupled between the fourth connection node 116 and the first common connection node 74. In another embodiment of the RF communications circuitry 54, the first RF antenna 16 is omitted. Additionally, the RF receive circuitry 62 is coupled between the third connection node 114 and the RF system control circuitry 56, and the RF receive circuitry 62 is further coupled between the fourth connection node 116 and the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the third tunable RF filter path 110 is the first RF receive filter, such that the first RF antenna 16 forwards a first received RF signal via the first common connection node 74 to provide the first upstream RF receive signal RU1 to the third tunable RF filter path 110, which receives and filters the first upstream RF receive signal RU1 to provide the first filtered RF receive signal RF1 to the RF receive circuitry 62. Additionally, the fourth tunable RF filter path 112 is a second RF receive filter, such that the first RF antenna 16 forwards a second received RF signal via the first common connection node 74 to provide the second upstream RF receive signal RU2 to the fourth tunable RF filter path 112, which receives and filters the second upstream RF receive signal RU2 to provide the second filtered RF receive signal RF2 to the RF receive circuitry 62.

The RF receive circuitry 62 may include down-conversion circuitry, amplification circuitry, power supply circuitry, filtering circuitry, switching circuitry, combining circuitry, splitting circuitry, dividing circuitry, clocking circuitry, the like, or any combination thereof. The RF receive circuitry 62 processes the first filtered RF receive signal RF1 to provide the first receive signal RX1 to the RF system control circuitry 56. Additionally, the RF receive circuitry 62 processes the second filtered RF receive signal RF2 to provide the second receive signal RX2 to the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, and the fourth tunable RF filter path 112 do not significantly load one another at frequencies of interest. As such, by directly coupling the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, and the fourth tunable RF filter path 112 to the first common connection node 74; front-end RF switching elements may be avoided, thereby reducing cost, size, and non-linearity; and increasing efficiency and flexibility of the RF communications circuitry 54.

In this regard, in one embodiment of the third tunable RF filter path 110 and the fourth tunable RF filter path 112, each of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a bandpass filter having a unique center frequency. As such, the first filter parameter of each of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a unique center frequency.

In an alternate embodiment of the third tunable RF filter path 110 and the fourth tunable RF filter path 112, one of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a lowpass filter, and another of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a highpass filter. As such, the first filter parameter of each of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a break frequency.

In an additional embodiment of the third tunable RF filter path 110 and the fourth tunable RF filter path 112, one of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a lowpass filter, and another of the third tunable RF filter path 110 and the fourth tunable RF filter

21

path 112 is a bandpass filter. As such, the first filter parameter of one of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a center frequency, and the first filter parameter of another of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a break frequency.

In an additional embodiment of the third tunable RF filter path 110 and the fourth tunable RF filter path 112, one of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a highpass filter, and another of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a bandpass filter. As such, the first filter parameter of one of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a center frequency, and the first filter parameter of another of the third tunable RF filter path 110 and the fourth tunable RF filter path 112 is a break frequency.

In one embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is a CA system, such that the third tunable RF filter path 110, which is the first RF receive filter, and the fourth tunable RF filter path 112, which is the second RF receive filter, simultaneously receive and filter the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2, respectively, via the first common connection node 74. As such, the first RF filter structure 60 functions as a de-multiplexer using the third tunable RF filter path 110 and the fourth tunable RF filter path 112. In one embodiment of the first RF filter structure 60, the first RF filter structure 60 further functions as a multiplexer using the first tunable RF filter path 66 and the second tunable RF filter path 68. In this regard, each of the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2 has a unique carrier frequency.

In another embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is a receive communications system, such that the third tunable RF filter path 110, which is the first RF receive filter, and the fourth tunable RF filter path 112, which is the second RF receive filter, do not simultaneously receive and filter the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2, respectively. As such, the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2 are nonsimultaneous signals. Each of the first upstream RF receive signal RU1 and the second upstream RF receive signal RU2 may be associated with a unique RF communications band.

FIG. 12 shows the RF communications circuitry 54 according to an alternate embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 12 is similar to the RF communications circuitry 54 illustrated in FIG. 11, except the RF communications circuitry 54 illustrated in FIG. 12 further includes the second RF antenna 32. Additionally, the RF front-end circuitry 58 further includes a second common connection node 118 and a second RF filter structure 120. The third tunable RF filter path 110 and the fourth tunable RF filter path 112 are included in the second RF filter structure 120 instead of being included in the first RF filter structure 60. Instead of being coupled to the first common connection node 74, the third tunable RF filter path 110 and the fourth tunable RF filter path 112 are coupled to the second common connection node 118. In one embodiment of the third tunable RF filter path 110 and the fourth tunable RF filter path 112, the third tunable RF filter path 110 and the fourth tunable RF filter path 112 are directly coupled to the second common connection node 118. In one embodiment of the RF com-

22

munications circuitry 54, the second RF antenna 32 is coupled to the second common connection node 118.

FIG. 13 shows the RF communications circuitry 54 according to an additional embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 13 is similar to the RF communications circuitry 54 illustrated in FIG. 12, except in the RF communications circuitry 54 illustrated in FIG. 13, the RF front-end control circuitry 98 provides a front-end status signal FES to the RF system control circuitry 56. Additionally, the RF front-end control circuitry 98 provides a first calibration control signal CCS1 and up to and including an  $N^{TH}$  calibration control signal CCSN to the first RF filter structure 60. The RF front-end control circuitry 98 provides a  $P^{TH}$  calibration control signal CCSP and up to and including an  $X^{TH}$  calibration control signal CCSX to the second RF filter structure 120. Details of the first RF filter structure 60 and the second RF filter structure 120 are not shown to simplify FIG. 13.

The first RF filter structure 60 provides a first calibration status signal CSS1 and up to and including a  $Q^{TH}$  calibration status signal CSSQ to the RF front-end control circuitry 98. The second RF filter structure 120 provides an  $R^{TH}$  calibration status signal CSSR and up to and including a  $Y^{TH}$  calibration status signal CSSY to the RF front-end control circuitry 98. In an alternate embodiment of the RF front-end circuitry 58, any or all of the  $N^{TH}$  calibration control signal CCSN, the  $Q^{TH}$  calibration status signal CSSQ, the  $X^{TH}$  calibration control signal CCSX, and the  $Y^{TH}$  calibration status signal CSSY are omitted.

In one embodiment of the RF front-end circuitry 58, the RF front-end circuitry 58 operates in one of a normal operating mode and a calibration mode. During the calibration mode, the RF front-end control circuitry 98 performs a calibration of the first RF filter structure 60, the second RF filter structure 120, or both. As such, the RF front-end control circuitry 98 provides any or all of the filter control signals FCS1, FCS2, FCS3, FCS4 and any or all of the calibration control signals CCS1, CCSN, CCSP, CCSX needed for calibration. Further, the RF front-end control circuitry 98 receives any or all of the calibration status signals CSS1, CSSQ, CSSR, CSSY needed for calibration.

During the normal operating mode, the RF front-end control circuitry 98 provides any or all of the filter control signals FCS1, FCS2, FCS3, FCS4 and any or all of the calibration control signals CCS1, CCSN, CCSP, CCSX needed for normal operation. Further, the RF front-end control circuitry 98 receives any or all of the calibration status signals CSS1, CSSQ, CSSR, CSSY needed for normal operation. Any or all of the calibration control signals CCS1, CCSN, CCSP, CCSX may be based on the front-end control signal FEC. The front-end status signal FES may be based on any or all of the calibration status signals CSS1, CSSQ, CSSR, CSSY. Further, during the normal operating mode, the RF front-end circuitry 58 processes signals as needed for normal operation. Other embodiments described in the present disclosure may be associated with normal operation.

The RF communications circuitry 54 illustrated in FIG. 13 includes the first RF antenna 16 and the second RF antenna 32. In general, the RF communications circuitry 54 is a multiple antenna system. A single-input single-output (SISO) antenna system is a system in which RF transmit signals may be transmitted from the first RF antenna 16 and RF receive signals may be received via the second RF antenna 32. In one embodiment of the RF communications

23

circuitry 54, the antenna system in the RF communications circuitry 54 is a SISO antenna system, as illustrated in FIG. 13.

A single-input multiple-output (SIMO) antenna system is a system in which RF transmit signals may be simultaneously transmitted from the first RF antenna 16 and the second RF antenna 32, and RF receive signals may be received via the second RF antenna 32. In an alternate embodiment of the RF communications circuitry 54, the second RF filter structure 120 is coupled to the RF transmit circuitry 64, such that the antenna system in the RF communications circuitry 54 is a SIMO antenna system.

A multiple-input single-output (MISO) antenna system is a system in which RF transmit signals may be transmitted from the first RF antenna 16, and RF receive signals may be simultaneously received via the first RF antenna 16 and the second RF antenna 32. In an additional embodiment of the RF communications circuitry 54, the first RF filter structure 60 is coupled to the RF receive circuitry 62, such that the antenna system in the RF communications circuitry 54 is a MISO antenna system.

A multiple-input multiple-output (MIMO) antenna system is a system in which RF transmit signals may be simultaneously transmitted from the first RF antenna 16 and the second RF antenna 32, and RF receive signals may be simultaneously received via the first RF antenna 16 and the second RF antenna 32. In another embodiment of the RF communications circuitry 54, the second RF filter structure 120 is coupled to the RF transmit circuitry 64 and the first RF filter structure 60 is coupled to the RF receive circuitry 62, such that the antenna system in the RF communications circuitry 54 is a MIMO antenna system.

FIG. 14 shows the RF communications circuitry 54 according to another embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 14 is similar to the RF communications circuitry 54 illustrated in FIG. 11, except in the RF communications circuitry 54 illustrated in FIG. 14, the first RF filter structure 60 further includes a fifth tunable RF filter path 122 and a sixth tunable RF filter path 124, and the RF front-end circuitry 58 further includes a fifth connection node 126 and a sixth connection node 128. Additionally, the RF front-end control circuitry 98 shown in FIG. 11 is not shown in FIG. 14 to simplify FIG. 14.

In one embodiment of the fifth tunable RF filter path 122, the fifth tunable RF filter path 122 includes a fifth pair (not shown) of weakly coupled resonators. In one embodiment of the sixth tunable RF filter path 124, the sixth tunable RF filter path 124 includes a sixth pair (not shown) of weakly coupled resonators.

In one embodiment of the fifth tunable RF filter path 122 and the sixth tunable RF filter path 124, the fifth tunable RF filter path 122 is directly coupled between the first common connection node 74 and the fifth connection node 126, and the sixth tunable RF filter path 124 is directly coupled between the sixth connection node 128 and the first common connection node 74. In another embodiment of the RF communications circuitry 54, the first RF antenna 16 is omitted. Additionally, the RF receive circuitry 62 is further coupled between the sixth connection node 128 and the RF system control circuitry 56, and the RF transmit circuitry 64 is further coupled between the fifth connection node 126 and the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the sixth tunable RF filter path 124 is a third RF receive filter, such that the first RF antenna 16 forwards a third received RF signal via the first common connection node 74

24

to provide a third upstream RF receive signal RU3 to the sixth tunable RF filter path 124, which receives and filters the third upstream RF receive signal RU3 to provide a third filtered RF receive signal RF3 to the RF receive circuitry 62, which processes the third filtered RF receive signal RF3 to provide the third receive signal RX3 to the RF system control circuitry 56.

In one embodiment of the RF communications circuitry 54, the fifth tunable RF filter path 122 is a third RF transmit filter, such that the RF system control circuitry 56 provides a third transmit signal TX3 to the RF transmit circuitry 64, which processes the third transmit signal TX3 to provide a third upstream RF transmit signal TU3 to the fifth tunable RF filter path 122. The fifth tunable RF filter path 122 receives and filters the third upstream RF transmit signal TU3 to provide a third filtered RF transmit signal TF3, which is transmitted via the first common connection node 74 by the first RF antenna 16.

In one embodiment of the RF communications circuitry 54, the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124 do not significantly load one another at frequencies of interest. Therefore, antenna switching circuitry 34, 42 (FIG. 3) may be avoided. As such, by directly coupling the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122 and the sixth tunable RF filter path 124 to the first common connection node 74, front-end RF switching elements may be avoided, thereby reducing cost, size, and non-linearity; and increasing efficiency and flexibility of the RF communications circuitry 54.

In one embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is an FDD communications system, such that each of the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124 is a bandpass filter having a unique center frequency. As such, in one embodiment of the RF system control circuitry 56, the first filter parameter of each of the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124 is a unique center frequency.

FIG. 15 shows the RF communications circuitry 54 according to a further embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 15 is similar to the RF communications circuitry 54 illustrated in FIG. 4, except in the RF communications circuitry 54 illustrated in FIG. 15, the RF front-end circuitry 58 further includes an RF antenna switch 130 and the third connection node 114. Additionally, the first RF filter structure 60 further includes the third tunable RF filter path 110. Instead of the first RF antenna 16 being directly coupled to the first common connection node 74, as illustrated in FIG. 4, the RF antenna switch 130 is coupled between the first RF antenna 16 and the first common connection node 74. As such, the first common connection node 74 is coupled to the first RF antenna 16 via the RF antenna switch 130. In this regard, the RF communications circuitry 54 is a hybrid RF communications system.

The RF antenna switch 130 has an antenna switch common connection node 132, an antenna switch first connection node 134, an antenna switch second connection node

25

136, and an antenna switch third connection node 138. The antenna switch common connection node 132 is coupled to the first RF antenna 16. In one embodiment of the RF antenna switch 130, the antenna switch common connection node 132 is directly coupled to the first RF antenna 16. The antenna switch first connection node 134 is coupled to the first common connection node 74. In one embodiment of the RF antenna switch 130, the antenna switch first connection node 134 is directly coupled to the first common connection node 74. The antenna switch second connection node 136 may be coupled to other circuitry (not shown). The antenna switch third connection node 138 may be coupled to other circuitry (not shown). In another embodiment of the RF antenna switch 130, the antenna switch third connection node 138 is omitted. In a further embodiment of the RF antenna switch 130, the RF antenna switch 130 has at least one additional connection node.

The RF system control circuitry 56 provides a switch control signal SCS to the RF antenna switch 130. As such, the RF system control circuitry 56 selects one of the antenna switch first connection node 134, the antenna switch second connection node 136, and the antenna switch third connection node 138 to be coupled to the antenna switch common connection node 132 using the switch control signal SCS.

The third tunable RF filter path 110 is directly coupled between the first common connection node 74 and the third connection node 114. In one embodiment of the RF communications circuitry 54, the third tunable RF filter path 110 is a second RF receive filter, such that the first RF antenna 16 forwards a received RF signal via the RF antenna switch 130 and the first common connection node 74 to provide the second upstream RF receive signal RU2 to the third tunable RF filter path 110, which receives and filters the second upstream RF receive signal RU2 to provide the second filtered RF receive signal RF2 to the RF receive circuitry 62. The RF receive circuitry 62 processes the second filtered RF receive signal RF2 to provide a second receive signal RX2 to the RF system control circuitry 56.

The RF system control circuitry 56 further provides the third filter control signal FCS3. As such, in one embodiment of the RF communications circuitry 54, the RF system control circuitry 56 tunes a first filter parameter of the third tunable RF filter path 110 using the third filter control signal FCS3. In one embodiment of the RF communications circuitry 54, the RF communications circuitry 54 uses the second tunable RF filter path 68 and the third tunable RF filter path 110 to provide receive CA. In an alternate embodiment of the RF communications circuitry 54, tunable RF filters allow for sharing a signal path to provide both an FDD signal path and a TDD signal path, thereby lowering front-end complexity.

FIG. 16 shows the RF communications circuitry 54 according to one embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 16 is similar to the RF communications circuitry 54 illustrated in FIG. 15, except in the RF communications circuitry 54 illustrated in FIG. 16, the third tunable RF filter path 110 is omitted. Additionally, in one embodiment of the RF communications circuitry 54, the RF receive circuitry 62, the RF transmit circuitry 64, and the first RF filter structure 60 are all broadband devices. As such, the RF communications circuitry 54 is broadband circuitry capable of processing RF signals having wide frequency ranges.

FIG. 17 shows the RF communications circuitry 54 according to an alternate embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 17 is similar to the RF communications

26

circuitry 54 illustrated in FIG. 16, except in the RF communications circuitry 54 illustrated in FIG. 17, the RF receive circuitry 62 is omitted and the RF front-end circuitry 58 further includes a first RF front-end circuit 140, a second RF front-end circuit 142, and a third RF front-end circuit 144.

The first RF front-end circuit 140 includes the RF transmit circuitry 64. The second RF front-end circuit 142 includes the first RF filter structure 60, the first connection node 70, the second connection node 72, and the first common connection node 74. The third RF front-end circuit 144 includes the RF antenna switch 130. In one embodiment of the first RF front-end circuit 140, the first RF front-end circuit 140 is a first RF front-end integrated circuit (IC). In one embodiment of the second RF front-end circuit 142, the second RF front-end circuit 142 is a second RF front-end IC. In one embodiment of the third RF front-end circuit 144, the third RF front-end circuit 144 is a third RF front-end IC.

FIG. 18 shows the RF communications circuitry 54 according to an additional embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 18 is similar to the RF communications circuitry 54 illustrated in FIG. 16, except in the RF communications circuitry 54 illustrated in FIG. 18, the RF receive circuitry 62 is omitted and the RF front-end circuitry 58 further includes the first RF front-end circuit 140 and the second RF front-end circuit 142.

The first RF front-end circuit 140 includes the RF transmit circuitry 64. The second RF front-end circuit 142 includes the first RF filter structure 60, the RF antenna switch 130, the first connection node 70, the second connection node 72, and the first common connection node 74. In one embodiment of the first RF front-end circuit 140, the first RF front-end circuit 140 is the first RF front-end IC. In one embodiment of the second RF front-end circuit 142, the second RF front-end circuit 142 is the second RF front-end IC.

FIG. 19 shows the RF communications circuitry 54 according to another embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 19 is similar to the RF communications circuitry 54 illustrated in FIG. 16, except in the RF communications circuitry 54 illustrated in FIG. 19, the RF receive circuitry 62 is omitted and the RF front-end circuitry 58 further includes the first RF front-end circuit 140.

The first RF front-end circuit 140 includes the RF transmit circuitry 64, the first RF filter structure 60, the RF antenna switch 130, the first connection node 70, the second connection node 72, and the first common connection node 74. In one embodiment of the first RF front-end circuit 140, the first RF front-end circuit 140 is the first RF front-end IC.

FIG. 20 shows the RF communications circuitry 54 according to a further embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 20 is a TDD system, which is capable of transmitting and receiving RF signals, but not simultaneously. As such, the RF communications circuitry 54 illustrated in FIG. 20 is similar to the RF communications circuitry 54 illustrated in FIG. 4, except in the RF communications circuitry 54 illustrated in FIG. 20, the second tunable RF filter path 68 and the second connection node 72 are omitted, and the RF front-end circuitry 58 further includes an RF transmit/receive switch 146 coupled between the first tunable RF filter path 66 and the RF receive circuitry 62, and further coupled between the first tunable RF filter path 66 and the RF transmit circuitry 64.

Since the RF communications circuitry 54 does not simultaneously transmit and receive RF signals, the first tunable

RF filter path 66 provides front-end transmit filtering when the RF communications circuitry 54 is transmitting RF signals and the first tunable RF filter path 66 provides front-end receive filtering when the RF communications circuitry 54 is receiving RF signals. In this regard, the first tunable RF filter path 66 processes half-duplex signals.

The RF transmit/receive switch 146 has a transmit/receive switch common connection node 148, a transmit/receive switch first connection node 150, and a transmit/receive switch second connection node 152. The RF receive circuitry 62 is coupled between the RF system control circuitry 56 and the transmit/receive switch second connection node 152. The RF transmit circuitry 64 is coupled between the RF system control circuitry 56 and the transmit/receive switch first connection node 150. The first connection node 70 is coupled to the transmit/receive switch common connection node 148.

The RF system control circuitry 56 provides a switch control signal SCS to the RF transmit/receive switch 146. As such, the RF system control circuitry 56 selects either the transmit/receive switch first connection node 150 or the transmit/receive switch second connection node 152 to be coupled to the transmit/receive switch common connection node 148 using the switch control signal SCS. Therefore, when the RF communications circuitry 54 is transmitting RF signals, the RF transmit circuitry 64 is coupled to the first tunable RF filter path 66 and the RF receive circuitry 62 is not coupled to the first tunable RF filter path 66. Conversely, when the RF communications circuitry 54 is receiving RF signals, the RF receive circuitry 62 is coupled to the first tunable RF filter path 66 and the RF transmit circuitry 64 is not coupled to the first tunable RF filter path 66.

FIG. 21 illustrates an exemplary embodiment of the first RF filter structure 60. The first RF filter structure 60 includes a plurality of resonators (referred to generically as elements R and specifically as elements  $R(i,j)$ , where an integer  $i$  indicates a row position and an integer  $j$  indicates a column position, where  $1 \leq i \leq M$ ,  $1 \leq j \leq N$  and  $M$  is any integer greater than 1 and  $N$  is any integer greater than 1. It should be noted that in alternative embodiments the number of resonators R in each row and column may be the same or different). The first tunable RF filter path 66 includes row 1 of weakly coupled resonators  $R(1,1)$ ,  $R(1,2)$  through  $R(1,N)$ . All of the weakly coupled resonators  $R(1,1)$ ,  $R(1,2)$  through  $R(1,N)$  are weakly coupled to one another. Furthermore, the first tunable RF filter path 66 is electrically connected between terminal 200 and terminal 202. In this manner, the first tunable RF filter path 66 is configured to receive RF signals and output filtered RF signals. The second tunable RF filter path 68 includes row M of weakly coupled resonators  $R(M,1)$ ,  $R(M,2)$  through  $R(M,N)$ . All of the weakly coupled resonators  $R(M,1)$ ,  $R(M,2)$  through  $R(M,N)$  are weakly coupled to one another. Furthermore, the second tunable RF filter path 68 is electrically connected between terminal 204 and terminal 206. In this manner, the second tunable RF filter path 68 is configured to receive RF signals and output filtered RF signals. It should be noted that the first RF filter structure 60 may include any number of tunable RF filter paths, such as, for example, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124, described above with respect to FIGS. 11-14. Each of the resonators R may be a tunable resonator, which allows for a resonant frequency of each of the resonators R to be varied to along a frequency range. In some embodiments, not all of the couplings between the resonators R are weak. A hybrid architecture having at least

one pair of weakly coupled resonators R and strongly or moderately coupled resonators R is also possible.

Cross-coupling capacitive structures C are electrically connected to and between the resonators R. In this embodiment, each of the cross-coupling capacitive structures C is a variable cross-coupling capacitive structure, such as a varactor or an array of capacitors. To be independent, the magnetic couplings may be negligible. Alternatively, the cross-coupling capacitive structures C may simply be provided by a capacitor with a fixed capacitance. With regard to the exemplary embodiment shown in FIG. 21, the tunable RF filter paths of the first RF filter structure 60 are independent of one another. As such, the first tunable RF filter path 66 and the second tunable RF filter path 68 are independent of one another and thus do not have cross-coupling capacitive structures C between their resonators. Thus, in this embodiment, the cross-coupling capacitive structures C do not connect any of the weakly coupled resonators  $R(1,1)$ ,  $R(1,2)$  through  $R(1,N)$  to any of the weakly coupled resonators  $R(M,1)$ ,  $R(M,2)$  through  $R(M,N)$ . This provides increased isolation between the first tunable RF filter path 66 and the second tunable RF filter path 68. In general, energy transfer between two weakly coupled resonators R in the first tunable RF filter path 66 and the second tunable RF filter path 68 may be provided by multiple energy transfer components. For example, energy may be transferred between the resonators R only through mutual magnetic coupling, only through mutual electric coupling, or through both mutual electric coupling and mutual magnetic coupling. Ideally, all of the mutual coupling coefficients are provided as designed, but in practice, the mutual coupling coefficients also be the result of parasitics. The inductors of the resonators R may also have magnetic coupling between them. A total coupling between the resonators R is given by the sum of magnetic and electric coupling.

In order to provide the transfer functions of the tunable RF filter paths 66, 68 with high out-of-band attenuation and a relatively low filter order, the tunable RF filter paths 66, 68 are configured to adjust notches in the transfer function, which are provided by the resonators R within the tunable RF filter paths 66, 68. The notches can be provided using parallel tanks connected in series or in shunt along a signal path of the first tunable RF filter path 66. To provide the notches, the parallel tanks operate approximately as an open circuit or as short circuits at certain frequencies. The notches can also be provided using multi-signal path cancellation. In this case, the tunable RF filter paths 66, 68 may be smaller and/or have fewer inductors. To tune the total mutual coupling coefficients between the resonators R towards a desired value, the tunable RF filter paths 66, 68 are configured to vary variable electric coupling coefficients so that parasitic couplings between the resonators R in the tunable RF filter paths 66, 68 are absorbed into a desired frequency transfer function.

FIG. 22 illustrates an exemplary embodiment of the first tunable RF filter path 66 in the first RF filter structure 60 shown in FIG. 21. While the exemplary embodiment shown in FIG. 22 is of the first tunable RF filter path 66, any of the tunable RF filter paths shown in the first RF filter structure 60 of FIG. 21 may be arranged in accordance with the exemplary embodiment shown in FIG. 22. The first tunable RF filter path 66 shown in FIG. 22 includes an embodiment of the resonator  $R(1,1)$  and an embodiment of the resonator  $R(1,2)$ . The resonator  $R(1,1)$  and the resonator  $R(1,2)$  are weakly coupled to one another. More specifically, the resonator  $R(1,1)$  includes an inductor 208 and a capacitive

structure 210. The resonator R(1,2) includes an inductor 212, a capacitive structure 214, and a capacitive structure 216.

The resonator R(1,1) and the resonator R(1,2) are a pair of weakly coupled resonators. The resonator R(1,1) and the resonator R(1,2) are weakly coupled by providing the inductor 208 and the inductor 212 such that the inductor 208 and the inductor 212 are weakly magnetically coupled. Although the resonator R(1,1) and the resonator R(1,2) are weakly coupled, the inductor 212 has a maximum lateral width and a displacement between the inductor 208 and the inductor 212 is less than or equal to half the maximum lateral width of the inductor 212. As such, the inductor 208 and the inductor 212 are relatively close to one another. The displacement between the inductor 208 and the inductor 212 may be measured from a geometric centroid of the inductor 208 to a geometric centroid of the inductor 212. The maximum lateral width may be a maximum dimension of the inductor 212 along a plane defined by its largest winding. The weak coupling between the inductor 208 and the inductor 212 is obtained through topological techniques. For example, the inductor 208 and the inductor 212 may be fully or partially aligned, where winding(s) of the inductor 208 and winding(s) of the inductor 212 are configured to provide weak coupling through cancellation. Alternatively or additionally, a plane defining an orientation of the winding(s) of the inductor 208 and a plane defining an orientation of the winding(s) of the inductor 212 may be fully or partially orthogonal to one another. Some of the magnetic couplings between the resonators R can be unidirectional (passive or active). This can significantly improve isolation (e.g., transmit and receive isolation in duplexers).

To maximize the quality (Q) factor of the tunable RF filter paths 66 through 68, most of the total mutual coupling should be realized magnetically, and only fine-tuning is provided electrically. This also helps to reduce common-mode signal transfer in the differential resonators and thus keeps the Q factor high. While the magnetic coupling can be adjusted only statically, with a new layout design, the electric coupling can be tuned on the fly (after fabrication). The filter characteristics (e.g., bias network structure, resonator capacitance) can be adjusted based on given coupling coefficients to maximize filter performance.

To provide a tuning range to tune a transfer function of the first tunable RF filter path 66 and provide a fast roll-off from a low-frequency side to a high-frequency side of the transfer function, the first tunable RF filter path 66 is configured to change a sign of a total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2). Accordingly, the first tunable RF filter path 66 includes a cross-coupling capacitive structure C(P1) and a cross-coupling capacitive structure C(N1). The cross-coupling capacitive structure C(P1) and the cross-coupling capacitive structure C(N1) are embodiments of the cross-coupling capacitive structures C described above with regard to FIG. 21. As shown in FIG. 22, the cross-coupling capacitive structure C(P1) is electrically connected between the resonator R(1,1) and the resonator R(1,2) so as to provide a positive coupling coefficient between the resonator R(1,1) and the resonator R(1,2). The cross-coupling capacitive structure C(P1) is a variable cross-coupling capacitive structure configured to vary the positive coupling coefficient provided between the resonator R(1,1) and the resonator R(1,2). The cross-coupling capacitive structure C(N1) is electrically connected between the resonator R(1,1) and the resonator R(1,2) so as to provide a negative coupling coefficient between the resonator R(1,1) and the resonator R(1,2). The cross-coupling capacitive

structure C(N1) is a variable cross-coupling capacitive structure configured to vary the negative coupling coefficient provided between the resonator R(1,1) and the resonator R(1,2). The arrangement of the cross-coupling capacitive structure C(P1) and the cross-coupling capacitive structure C(N1) shown in FIG. 22 is a V-bridge structure. In alternative embodiments, some or all of the cross-coupling capacitive structures is fixed (not variable).

In the resonator R(1,1), the inductor 208 and the capacitive structure 210 are electrically connected in parallel. More specifically, the inductor 208 has an end 217 and an end 218, which are disposed opposite to one another. The ends 217, 218 are each electrically connected to the capacitive structure 210, which is grounded. Thus, the resonator R(1,1) is a single-ended resonator. On the other hand, the inductor 212 is electrically connected between the capacitive structure 214 and the capacitive structure 216. More specifically, the inductor 212 has an end 220 and an end 222, which are disposed opposite to one another. The end 220 is electrically connected to the capacitive structure 214 and the end 222 is electrically connected to the capacitive structure 216. Both the capacitive structure 214 and the capacitive structure 216 are grounded. Thus, the resonator R(1,2) is a differential resonator. In an alternative, an inductor with a center tap can be used. The tap can be connected to ground and only a single capacitive structure can be used. In yet another embodiment, both an inductor and a capacitive structure may have a center tap that is grounded. In still another embodiment, neither the inductor nor the capacitive structure may have a grounded center tap.

The inductor 208 is magnetically coupled to the inductor 212 such that an RF signal received at the end 217 of the inductor 208 with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in a filtered RF signal being transmitted out the end 220 of the inductor 212 with the same voltage polarity. Also, the inductor 212 is magnetically coupled to the inductor 208 such that an RF signal received at the end 220 of the inductor 212 with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in a filtered RF signal being transmitted out the end 217 of the inductor 208 with the same voltage polarity. This is indicated in FIG. 22 by the dot convention where a dot is placed at the end 217 of the inductor 208 and a dot is placed at the end 220 of the inductor 212. By using two independent and adjustable coupling coefficients (i.e., the positive coupling coefficient and the negative coupling coefficient) with the resonator R(1,2) (i.e., the differential resonator), the transfer function of the first tunable RF filter path 66 is provided so as to be fully adjustable. More specifically, the inductors 208, 212 may be magnetically coupled so as to have a low magnetic coupling coefficient through field cancellation, with the variable positive coupling coefficient and the variable negative coupling coefficient. In this case, the inductor 208 and the inductor 212 are arranged such that a mutual magnetic coupling between the inductor 208 and the inductor 212 cancel. Alternatively, the inductor 208 and the inductor 212 are arranged such that the inductor 212 reduces a mutual magnetic coupling coefficient of the inductor 208. With respect to the magnetic coupling coefficient, the variable positive coupling coefficient is a variable positive electric coupling coefficient and the variable negative coupling coefficient is a variable negative electric coupling coefficient. The variable positive electric coupling coefficient and the variable negative electric coupling coefficient oppose each other to create a tunable filter characteristic.

31

The resonator R(1,2) is operably associated with the resonator R(1,1) such that an energy transfer factor between the resonator R(1,1) and the resonator R(1,2) is less than 10%. A total mutual coupling between the resonator R(1,1) and the resonator R(1,2) is provided by a sum total of the mutual magnetic factor between the resonator R(1,1) and the resonator R(1,2) and the mutual electric coupling coefficients between the resonator R(1,1) and the resonator R(1,2). In this embodiment, the mutual magnetic coupling coefficient between the inductor 208 and the inductor 212 is a fixed mutual magnetic coupling coefficient. Although embodiments of the resonators R(1,1), R(1,2) may be provided so as to provide a variable magnetic coupling coefficient between the resonators R(1,1), R(1,2), embodiments of the resonators R(1,1), R(1,2) that provide variable magnetic couplings can be costly and difficult to realize. However, providing variable electric coupling coefficients (i.e., the variable positive electric coupling coefficient and the variable electric negative coupling coefficient) is easier and more economical. Thus, using the cross-coupling capacitive structure C(P1) and the cross-coupling capacitive structure C(N1) to provide the variable positive electric coupling coefficient and the variable electric negative coupling coefficient is an economical technique for providing a tunable filter characteristic between the resonators R(1,1), R(1,2). Furthermore, since the mutual magnetic coupling coefficient between the inductor 208 and the inductor 212 is fixed, the first tunable RF filter path 66 has lower insertion losses.

In the embodiment shown in FIG. 22, the inductor 208 and the 212 inductor are the same size. Alternatively, the inductor 208 and the inductor 212 may be different sizes. For example, the inductor 212 may be smaller than the inductor 208. By determining a distance between the inductor 208 and the inductor 212, the magnetic coupling coefficient between the inductor 208 and the inductor 212 can be set. With regard to the inductors 208, 212 shown in FIG. 22, the inductor 208 may be a folded inductor configured to generate a first confined magnetic field, while the inductor 212 may be a folded inductor configured to generate a second confined magnetic field. Magnetic field lines of the first confined magnetic field and of the second confined magnetic field that are external to the inductor 208 and inductor 212 are cancelled by opposing magnetic field lines in all directions. When the inductor 208 and the inductor 212 are folded inductors, the folded inductors can be stacked. This allows building the first tunable RF filter path 66 such that several inductors 208, 212 are stacked. Furthermore, this arrangement allows for a specially sized interconnect structure that electrically connects the inductors 208, 212 to the capacitive structure 210, the capacitive structure 214, the capacitive structure 216, the cross-coupling capacitive structure C(P1), and the cross-coupling capacitive structure C(N1). The specially sized interconnect increases the Q factor of the capacitive structure 210, the capacitive structure 214, the capacitive structure 216, the cross-coupling capacitive structure C(P1), and the cross-coupling capacitive structure C(N1), and allows for precise control of their variable capacitances. Weakly coupled filters can also be realized with planar field cancellation structures.

FIG. 23 illustrates an exemplary embodiment of the first tunable RF filter path 66 in the first RF filter structure 60 shown in FIG. 21. While the exemplary embodiment shown in FIG. 23 is of the first tunable RF filter path 66, any of the tunable RF filter paths shown in the first RF filter structure 60 of FIG. 21 may be arranged in accordance with the exemplary embodiment shown in FIG. 23. The first tunable RF filter path 66 shown in FIG. 23 includes an embodiment

32

of the resonator R(1,1) and an embodiment of the resonator R(1,2). The resonator R(1,1) and the resonator R(1,2) are weakly coupled to one another. The embodiment of the resonator R(1,2) is the same as the embodiment of the resonator R(1,2) shown in FIG. 22. Thus, the resonator R(1,2) shown in FIG. 23 is a differential resonator that includes the inductor 212, the capacitive structure 214, and the capacitive structure 216. Additionally, like the embodiment of the resonator R(1,1) shown in FIG. 22, the embodiment of the resonator R(1,1) shown in FIG. 23 includes the inductor 208 and the capacitive structure 210. However, in this embodiment, the resonator R(1,1) shown in FIG. 23 is a differential resonator and further includes a capacitive structure 224. More specifically, the end 217 of the inductor 208 is electrically connected to the capacitive structure 210 and the end 218 of the inductor 208 is electrically connected to the capacitive structure 224. Both the capacitive structure 210 and the capacitive structure 224 are grounded. Like the capacitive structure 210, the capacitive structure 224 is also a variable capacitive structure, such as a programmable array of capacitors or a varactor. Alternatively, a center tap of an inductor may be grounded. In yet another embodiment, the inductor and a capacitive structure may be RF floating (a low-resistance connection to ground).

The resonator R(1,1) and the resonator R(1,2) are a pair of weakly coupled resonators. Like the first tunable RF filter path 66 shown in FIG. 22, the resonator R(1,1) and the resonator R(1,2) are weakly coupled by providing the inductor 208 and the inductor 212 such that the inductor 208 and the inductor 212 are weakly coupled. Thus, the inductor 208 and the inductor 212 may have a magnetic coupling coefficient that is less than or equal to approximately 0.3. Although the resonator R(1,1) and the resonator R(1,2) are weakly coupled, a displacement between the inductor 208 and the inductor 212 is less than or equal to half the maximum lateral width of the inductor 212. As such, the inductor 208 and the inductor 212 are relatively close to one another. The displacement between the inductor 208 and the inductor 212 may be measured from a geometric centroid of the inductor 208 to a geometric centroid of the inductor 212. The maximum lateral width may be a maximum dimension of the inductor 212 along a plane defined by its largest winding.

The weak coupling between the inductor 208 and the inductor 212 is obtained through topological techniques. For example, the inductor 208 and the inductor 212 may be fully or partially aligned, where winding(s) of the inductor 208 and winding(s) of the inductor 212 are configured to provide weak coupling through cancellation. Alternatively or additionally, a plane defining an orientation of the windings of the inductor 208 and a plane defining an orientation of the windings of the inductor 212 may be fully or partially orthogonal to one another.

The resonator R(1,2) is operably associated with the resonator R(1,1) such that an energy transfer factor between the resonator R(1,1) and the resonator R(1,2) is less than 10%. To provide a tuning range to tune a transfer function of the first tunable RF filter path 66 such to provide a fast roll-off from a low-frequency side to a high-frequency side requires changing a sign of the total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2). Like the embodiment of the first tunable RF filter path 66 shown in FIG. 22, the first tunable RF filter path 66 shown in FIG. 23 includes the cross-coupling capacitive structure C(P1) and the cross-coupling capacitive structure C(N1). The cross-coupling capacitive structure C(P1) and the cross-coupling capacitive structure C(N1) are arranged in the same

33

manner described above with respect to FIG. 22. However, in this embodiment, the first tunable RF filter path 66 shown in FIG. 23 also includes a cross-coupling capacitive structure C(P2) and a cross-coupling capacitive structure C(N2). The cross-coupling capacitive structure C(P2) and the cross-coupling capacitive structure C(N2) are also embodiments of the cross-coupling capacitive structures C described above with regard to FIG. 21.

As described above with respect to FIG. 22, the cross-coupling capacitive structure C(P1) is electrically connected between the resonator R(1,1) and the resonator R(1,2) so as to provide the positive coupling coefficient (i.e., the variable positive electric coupling coefficient) between the resonator R(1,1) and the resonator R(1,2). Also as described above with respect to FIG. 22, the cross-coupling capacitive structure C(N1) is electrically connected between the resonator R(1,1) and the resonator R(1,2) so as to provide the negative coupling coefficient (i.e., the variable negative electric coupling coefficient) between the resonator R(1,1) and the resonator R(1,2). With regard to the cross-coupling capacitive structure C(P2), the cross-coupling capacitive structure C(P2) is electrically connected between the resonator R(1,1) and the resonator R(1,2) so as to provide another positive coupling coefficient (i.e., another variable positive electric coupling coefficient) between the resonator R(1,1) and the resonator R(1,2). In this embodiment, the cross-coupling capacitive structure C(P2) is electrically connected between the end 218 of the inductor 208 and the end 222 of the inductor 212. The cross-coupling capacitive structure C(P2) is a variable cross-coupling capacitive structure configured to vary the other positive coupling coefficient (i.e., the other variable positive electric coupling coefficient) provided between the resonator R(1,1) and the resonator R(1,2). With regard to the cross-coupling capacitive structure C(N2), the cross-coupling capacitive structure C(N2) is electrically connected between the resonator R(1,1) and the resonator R(1,2) so as to provide another negative coupling coefficient (i.e., another variable negative electric coupling coefficient) between the resonator R(1,1) and the resonator R(1,2). In this embodiment, the cross-coupling capacitive structure C(N2) is electrically connected between the end 218 of the inductor 208 and the end 220 of the inductor 212. The cross-coupling capacitive structure C(N2) is a variable cross-coupling capacitive structure configured to vary the negative coupling coefficient (i.e., the other variable negative electric coupling coefficient) provided between the resonator R(1,1) and the resonator R(1,2). The arrangement of the cross-coupling capacitive structure C(P1), the cross-coupling capacitive structure C(N1), the cross-coupling capacitive structure C(P2), and the cross-coupling capacitive structure C(N2) shown in FIG. 23 is an X-bridge structure.

As shown in FIG. 23, the resonator R(1,2) is operably associated with the resonator R(1,1) such that an energy transfer factor between the resonator R(1,1) and the resonator R(1,2) is less than 10%. The total mutual coupling between the resonator R(1,1) and the resonator R(1,2) is provided by a sum total of the mutual magnetic factor between the resonator R(1,1) and the resonator R(1,2) and the mutual electric coupling coefficients between the resonator R(1,1) and the resonator R(1,2). Thus, in this embodiment, the total mutual coupling between the resonator R(1,1) and the resonator R(1,2) is provided by the sum total of the mutual magnetic coupling coefficient, the variable positive electric coupling coefficient provided by the cross-coupling capacitive structure C(P1), the variable negative electric coupling coefficient provided by the cross-coupling capacitive structure C(N1), the other variable positive electric

34

coupling coefficient provided by the cross-coupling capacitive structure C(P2), and the other variable negative electric coupling coefficient provided by the cross-coupling capacitive structure C(N2).

FIG. 24 illustrates an exemplary embodiment of the first tunable RF filter path 66 in the first RF filter structure 60 shown in FIG. 21. While the exemplary embodiment shown in FIG. 24 is of the first tunable RF filter path 66, any of the tunable RF filter paths shown in the first RF filter structure 60 of FIG. 21 may be arranged in accordance with the exemplary embodiment shown in FIG. 24. The first tunable RF filter path 66 shown in FIG. 24 includes an embodiment of the resonator R(1,1) and an embodiment of the resonator R(1,2). The resonator R(1,1) and the resonator R(1,2) are weakly coupled to one another. The embodiment of the resonator R(1,1) is the same as the embodiment of the resonator R(1,1) shown in FIG. 22. Thus, the resonator R(1,1) shown in FIG. 24 is a single-ended resonator that includes the inductor 208 and the capacitive structure 210. Additionally, like the embodiment of the resonator R(1,2) shown in FIG. 22, the embodiment of the resonator R(1,2) shown in FIG. 24 includes the inductor 212 and the capacitive structure 214. However, in this embodiment, the resonator R(1,2) shown in FIG. 24 is a single-ended resonator. More specifically, the end 220 and the end 222 of the inductor 212 are each electrically connected to the capacitive structure 214, which is grounded.

The resonator R(1,1) and the resonator R(1,2) are a pair of weakly coupled resonators. Like the first tunable RF filter path 66 shown in FIG. 22, the resonator R(1,1) and the resonator R(1,2) are weakly coupled by providing the inductor 208 and the inductor 212 such that the inductor 208 and the inductor 212 are weakly coupled. Thus, the inductor 208 and the inductor 212 may have a magnetic coupling coefficient that is less than or equal to approximately 0.3. Although the resonator R(1,1) and the resonator R(1,2) are weakly coupled, the displacement between the inductor 208 and the inductor 212 is less than or equal to half the maximum lateral width of the inductor 212. As such, the inductor 208 and the inductor 212 are relatively close to one another. The displacement between the inductor 208 and the inductor 212 may be measured from the geometric centroid of the inductor 208 to the geometric centroid of the inductor 212. The maximum lateral width may be a maximum dimension of the inductor 212 along a plane defined by its largest winding. The weak coupling between the inductor 208 and the inductor 212 is obtained through topological techniques. For example, the inductor 208 and the inductor 212 may be fully or partially aligned, where winding(s) of the inductor 208 and winding(s) of the inductor 212 are configured to provide weak coupling through cancellation. Alternatively or additionally, a plane defining an orientation of the windings of the inductor 208 and a plane defining an orientation of the windings of the inductor 212 may be fully or partially orthogonal to one another.

The resonator R(1,2) is operably associated with the resonator R(1,1) such that an energy transfer factor between the resonator R(1,1) and the resonator R(1,2) is less than 10%. To provide a tuning range to tune a transfer function of the first tunable RF filter path 66 and provide a fast roll-off from a low-frequency side to a high-frequency side of the transfer function, the first tunable RF filter path 66 is configured to change a sign of a total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2). However, in this embodiment, the first tunable RF filter path 66 shown in FIG. 24 only includes the cross-coupling capacitive structure C(P1), which is electrically

35

connected between the end 217 of the inductor 208 and the end 220 of the inductor 212. As discussed above with respect to FIGS. 22 and 23, the cross-coupling capacitive structure C(P1) is a variable cross-coupling capacitive structure configured to vary the positive coupling coefficient (i.e., the variable positive electric coupling coefficient) provided between the resonator R(1,1) and the resonator R(1,2). Thus, in order to allow for the sign of the total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2) to be changed, the inductor 208 and the inductor 212 are arranged so as to provide a fixed negative mutual magnetic coupling coefficient between the inductor 208 of the resonator R(1,1) and the inductor 212 of the resonator R(1,2). As such, varying the variable positive electric coupling coefficient allows for the sign of the total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2) to be changed using only the cross-coupling capacitive structure C(P1).

As such, in this embodiment, the inductor 208 is magnetically coupled to the inductor 212 such that an RF signal received at the end 217 of the inductor 208 with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in a filtered RF signal with the same voltage polarity being transmitted out the end 222 of the inductor 212. In addition, the inductor 212 is magnetically coupled to the inductor 208 such that an RF signal received at the end 222 of the inductor 212 with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in a filtered RF signal with the same voltage polarity being transmitted out the end 217 of the inductor 208. This is indicated in FIG. 24 by the dot convention where a dot is placed at the end 217 of the inductor 208 and a dot is placed at the end 222 of the inductor 212. By using the fixed negative mutual magnetic coupling coefficient and the variable positive electric coupling coefficient, the transfer function of the first tunable RF filter path 66 is provided so to be fully adjustable. The arrangement of the cross-coupling capacitive structure C(P1) shown in FIG. 24 is a single positive bridge structure.

FIG. 25 illustrates another exemplary embodiment of the first tunable RF filter path 66 in the first RF filter structure 60 shown in FIG. 21. While the exemplary embodiment shown in FIG. 25 is of the first tunable RF filter path 66, any of the tunable RF filter paths shown in the first RF filter structure 60 of FIG. 21 may be arranged in accordance with the exemplary embodiment shown in FIG. 25. The first tunable RF filter path 66 shown in FIG. 25 includes an embodiment of the resonator R(1,1) and an embodiment of the resonator R(1,2). The resonator R(1,1) and the resonator R(1,2) are weakly coupled to one another. The embodiment of the resonator R(1,1) is the same as the embodiment of the resonator R(1,1) shown in FIG. 22. Thus, the resonator R(1,1) shown in FIG. 25 is a single-ended resonator that includes the inductor 208 and the capacitive structure 210, which are arranged in the same manner described above with respect to FIG. 22. Like the resonator R(1,2) shown in FIG. 24, the resonator R(1,2) shown in FIG. 25 is a single-ended resonator that includes the inductor 212 and the capacitive structure 214. However, the inductor 208 shown in FIG. 25 is magnetically coupled to the inductor 212 such that an RF signal received at the end 217 of the inductor 208 with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in a filtered RF signal with the same voltage polarity being transmitted out the end 220 of the inductor 212. Also, the inductor 212 shown in FIG. 25 is magnetically coupled to the inductor 208 such that an RF signal received at the end 220 of the inductor 212

36

with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in a filtered RF signal with the same voltage polarity being transmitted out the end 217 of the inductor 208. This is indicated in FIG. 25 by the dot convention where a dot is placed at the end 217 of the inductor 208 and a dot is placed at the end 220 of the inductor 212. In alternative embodiments, the resonator R(1,2) is a differential resonator. In yet another alternative embodiment, the resonator R(1,1) is a single-ended resonator while the resonator R(1,2) is a differential resonator.

The resonator R(1,1) and the resonator R(1,2) are a pair of weakly coupled resonators. Like the first tunable RF filter path 66 shown in FIG. 22, the resonator R(1,1) and the resonator R(1,2) are weakly coupled by providing the inductor 208 and the inductor 212 such that the inductor 208 and the inductor 212 are weakly coupled. Thus, the inductor 208 and the inductor 212 may have a fixed magnetic coupling coefficient that is less than or equal to approximately 0.3. Although the resonator R(1,1) and the resonator R(1,2) are weakly coupled, a displacement between the inductor 208 and the inductor 212 is less than or equal to half the maximum lateral width of the inductor 212. As such, the inductor 208 and the inductor 212 are relatively close to one another. The displacement between the inductor 208 and the inductor 212 may be measured from a geometric centroid of the inductor 208 to a geometric centroid of the inductor 212. The maximum lateral width may be a maximum dimension of the inductor 212 along a plane defined by its largest winding.

The weak coupling between the inductor 208 and the inductor 212 is obtained through topological techniques. For example, the inductor 208 and the inductor 212 may be fully or partially aligned, where winding(s) of the inductor 208 and winding(s) of the inductor 212 are configured to provide weak coupling through cancellation. Alternatively or additionally, a plane defining an orientation of the windings of the inductor 208 and a plane defining an orientation of the windings of the inductor 212 may be fully or partially orthogonal to one another.

The resonator R(1,2) is operably associated with the resonator R(1,1) such that an energy transfer factor between the resonator R(1,1) and the resonator R(1,2) is less than 10%. To provide a tuning range to tune the transfer function of the first tunable RF filter path 66 and to provide a fast roll-off from the low-frequency side to the high-frequency side of the transfer function, the first tunable RF filter path 66 is configured to change the sign of the total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2). In this embodiment, the first tunable RF filter path 66 shown in FIG. 25 includes a cross-coupling capacitive structure C(PH1), a cross-coupling capacitive structure C(NH1), a cross-coupling capacitive structure C(I1), a cross-coupling capacitive structure C(PH2), and a cross-coupling capacitive structure C(NH2). The cross-coupling capacitive structure C(PH1), the cross-coupling capacitive structure C(NH1), the cross-coupling capacitive structure C(I1), the cross-coupling capacitive structure C(PH2), and the cross-coupling capacitive structure C(NH2) are also embodiments of the cross-coupling capacitive structures C described above with regard to FIG. 21.

The cross-coupling capacitive structure C(PH1) and the cross-coupling capacitive structure C(NH1) are arranged to form a first capacitive voltage divider. The first capacitive voltage divider is electrically connected to the resonator R(1,1). More specifically, the cross-coupling capacitive structure C(PH1) is electrically connected between the end 217 of the inductor 208 and a common connection node H1.

The cross-coupling capacitive structure C(NH1) is electrically connected between the end 218 of the inductor 208 and the common connection node H1. Additionally, the cross-coupling capacitive structure C(PH2) and the cross-coupling capacitive structure C(NH2) are arranged to form a second capacitive voltage divider. The second capacitive voltage divider is electrically connected to the resonator R(1,2). More specifically, the cross-coupling capacitive structure C(PH2) is electrically connected between the end 220 of the inductor 212 and a common connection node H2. The cross-coupling capacitive structure C(NH2) is electrically connected between the end 222 of the inductor 212 and the common connection node H2. As shown in FIG. 25, the cross-coupling capacitive structure C(I1) is electrically connected between the first capacitive voltage divider and the second capacitive voltage divider. More specifically, the cross-coupling capacitive structure C(I1) is electrically connected between the common connection node H1 and the common connection node H2. The arrangement of the cross-coupling capacitive structure C(PH1), the cross-coupling capacitive structure C(NH1), the cross-coupling capacitive structure C(PH2), the cross-coupling capacitive structure C(NH2), and the cross-coupling capacitive structure C(I1) shown in FIG. 25 is an H-bridge structure. In an alternative H-bridge structure, the cross-coupling capacitive structure C(I1) is not provided and instead there is a short between the common connection node H1 and the common connection node H2. In addition, a center tap of the inductor 208 may be grounded and/or the common connection node H1 may be grounded. Finally, a high impedance to ground may be provided at the common connection node H1.

With regard to the first capacitive voltage divider, the cross-coupling capacitive structure C(PH1) is a variable cross-coupling capacitive structure configured to vary a first variable positive electric coupling coefficient provided between the resonator R(1,1) and the common connection node H1. The cross-coupling capacitive structure C(NH1) is a variable cross-coupling capacitive structure configured to vary a first variable negative electric coupling coefficient provided between the resonator R(1,1) and the common connection node H1. Thus, a mutual electric coupling coefficient of the resonator R(1,1) is approximately equal to the first variable positive electric coupling coefficient and the first variable negative electric coupling coefficient.

With regard to the second capacitive voltage divider, the cross-coupling capacitive structure C(PH2) is a variable cross-coupling capacitive structure configured to vary a second variable positive electric coupling coefficient provided between the resonator R(1,2) and the common connection node H2. The cross-coupling capacitive structure C(NH2) is a variable cross-coupling capacitive structure configured to vary a second variable negative electric coupling coefficient provided between the resonator R(1,2) and the common connection node H2. Thus, a mutual electric coupling coefficient of the resonator R(1,2) is approximately equal to the second variable positive electric coupling coefficient and the second variable negative electric coupling coefficient. Furthermore, the cross-coupling capacitive structure C(I1) is a variable cross-coupling capacitive structure configured to vary a first variable intermediate electric coupling coefficient provided between the common connection node H1 and the common connection node H2. The first tunable RF filter path 66 shown in FIG. 25 thus has a total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2) equal to the sum total of the mutual magnetic coupling coefficient between the inductor 208 and the inductor 212, the mutual electric coupling coefficient of

the resonator R(1,1), the mutual electric coupling coefficient of the resonator R(1,2), and the first variable intermediate electric coupling coefficient provided between the common connection node H1 and the common connection node H2. In alternative embodiments, cross-coupling capacitive structures with fixed capacitances are provided.

In one embodiment, the cross-coupling capacitive structure C(PH1), the cross-coupling capacitive structure C(NH1), the cross-coupling capacitive structure C(PH2), the cross-coupling capacitive structure C(NH2), and the cross-coupling capacitive structure C(I1) may each be provided as a varactor. However, the cross-coupling capacitive structure C(PH1), the cross-coupling capacitive structure C(NH1), the cross-coupling capacitive structure C(PH2), the cross-coupling capacitive structure C(NH2), and the cross-coupling capacitive structure C(I1) may each be provided as a programmable array of capacitors in order to reduce insertion losses and improve linearity. The cross-coupling capacitive structure C(PH1), the cross-coupling capacitive structure C(NH1), the cross-coupling capacitive structure C(PH2), the cross-coupling capacitive structure C(NH2), and the cross-coupling capacitive structure C(I1) can also be any combination of suitable variable cross-coupling capacitive structures, such as combinations of varactors and programmable arrays of capacitors. Although the H-bridge structure can provide good linearity and low insertion losses, the H-bridge structure can also suffer from common-mode signal transfer.

FIG. 26 illustrates yet another exemplary embodiment of the first tunable RF filter path 66 in the first RF filter structure 60 shown in FIG. 21. While the exemplary embodiment shown in FIG. 26 is of the first tunable RF filter path 66, any of the tunable RF filter paths shown in the first RF filter structure 60 of FIG. 21 may be arranged in accordance with the exemplary embodiment shown in FIG. 26. The first tunable RF filter path 66 shown in FIG. 26 can be used to ameliorate the common-mode signal transfer of the H-bridge structure shown in FIG. 25. More specifically, the first tunable RF filter path 66 shown in FIG. 26 includes the same embodiment of the resonator R(1,1) and the same embodiment of the resonator R(1,2) described above with respect to FIG. 25. Furthermore, the first tunable RF filter path 66 shown in FIG. 26 includes the first capacitive voltage divider with the cross-coupling capacitive structure C(PH1) and the cross-coupling capacitive structure C(NH1) described above with respect to FIG. 25, the second capacitive voltage divider with the cross-coupling capacitive structure C(PH2) and the cross-coupling capacitive structure C(NH2) described above with respect to FIG. 25, and the cross-coupling capacitive structure C(I1) described above with respect to FIG. 25. However, in this embodiment, the first tunable RF filter path 66 shown in FIG. 26 also includes a cross-coupling capacitive structure C(PH3), a cross-coupling capacitive structure C(NH3), a cross-coupling capacitive structure C(I2), a cross-coupling capacitive structure C(PH4), and a cross-coupling capacitive structure C(NH4). The cross-coupling capacitive structure C(PH3), the cross-coupling capacitive structure C(NH3), the cross-coupling capacitive structure C(I2), the cross-coupling capacitive structure C(PH4), and the cross-coupling capacitive structure C(NH4) are also embodiments of the cross-coupling capacitive structures C described above with regard to FIG. 21.

As shown in FIG. 26, the cross-coupling capacitive structure C(PH3) and the cross-coupling capacitive structure C(NH3) are arranged to form a third capacitive voltage divider. The third capacitive voltage divider is electrically connected to the resonator R(1,1). More specifically, the

cross-coupling capacitive structure C(PH3) is electrically connected between the end 217 of the inductor 208 and a common connection node H3. The cross-coupling capacitive structure C(NH3) is electrically connected between the end 218 of the inductor 208 and the common connection node H3. Additionally, the cross-coupling capacitive structure C(PH4) and the cross-coupling capacitive structure C(NH4) are arranged to form a fourth capacitive voltage divider. The fourth capacitive voltage divider is electrically connected to the resonator R(1,2). More specifically, the cross-coupling capacitive structure C(PH4) is electrically connected between the end 220 of the inductor 212 and a common connection node H4. The cross-coupling capacitive structure C(NH4) is electrically connected between the end 222 of the inductor 212 and the common connection node H4. As shown in FIG. 26, the cross-coupling capacitive structure C(I2) is electrically connected between first capacitive voltage divider and the second capacitive voltage divider. More specifically, the cross-coupling capacitive structure C(I2) is electrically connected between the common connection node H3 and the common connection node H4. Alternatively, the cross-coupling capacitive structure C(I1) and the cross-coupling capacitive structure C(I2) can be replaced with shorts. The arrangement of the cross-coupling capacitive structure C(PH1), the cross-coupling capacitive structure C(NH1), the cross-coupling capacitive structure C(PH2), the cross-coupling capacitive structure C(NH2), the cross-coupling capacitive structure C(I1), the cross-coupling capacitive structure C(PH3), the cross-coupling capacitive structure C(NH3), the cross-coupling capacitive structure C(PH4), the cross-coupling capacitive structure C(NH4), and the cross-coupling capacitive structure C(I2) shown in FIG. 26 is a double H-bridge structure.

With regard to the third capacitive voltage divider, the cross-coupling capacitive structure C(PH3) is a variable cross-coupling capacitive structure configured to vary a third variable positive electric coupling coefficient provided between the resonator R(1,1) and the common connection node H3. The cross-coupling capacitive structure C(NH3) is a variable cross-coupling capacitive structure configured to vary a third variable negative electric coupling coefficient provided between the resonator R(1,1) and the common connection node H3. Thus, a mutual electric coupling coefficient of the resonator R(1,1) is approximately equal to the first variable positive electric coupling coefficient, the third variable positive electric coupling coefficient, the first variable negative electric coupling coefficient and the third variable negative electric coupling coefficient.

With regard to the fourth capacitive voltage divider, the cross-coupling capacitive structure C(PH4) is a variable cross-coupling capacitive structure configured to vary a fourth variable positive electric coupling coefficient provided between the resonator R(1,2) and the common connection node H4. The cross-coupling capacitive structure C(NH4) is a variable cross-coupling capacitive structure configured to vary a fourth variable negative electric coupling coefficient provided between the resonator R(1,2) and the common connection node H4. Thus, a mutual electric coupling coefficient of the resonator R(1,2) is approximately equal to the second variable positive electric coupling coefficient, the fourth variable positive coupling coefficient, the second variable negative coupling coefficient, and the fourth variable negative electric coupling coefficient. Furthermore, the cross-coupling capacitive structure C(I2) is a variable cross-coupling capacitive structure configured to vary a second variable intermediate electric coupling coefficient provided between the common connection node H3 and the

common connection node H4. The first tunable RF filter path 66 shown in FIG. 26 thus has a total mutual coupling coefficient between the resonator R(1,1) and the resonator R(1,2) equal to the sum total of the mutual magnetic coupling coefficient between the inductor 208 and the inductor 212, the mutual electric coupling coefficient of the resonator R(1,1), the mutual electric coupling coefficient of the resonator R(1,2), the first variable intermediate electric coupling coefficient provided between the common connection node H1 and the common connection node H2 and the second variable intermediate electric coupling coefficient provided between the common connection node H3 and the common connection node H4. The double H-bridge structure thus includes two H-bridge structures. The two H-bridge structures allow for common-mode signal transfers of the two H-bridge structures to oppose one another and thereby be reduced and even cancelled.

FIG. 27 illustrates still another exemplary embodiment of the first tunable RF filter path 66 in the first RF filter structure 60 shown in FIG. 21. While the exemplary embodiment shown in FIG. 27 is of the first tunable RF filter path 66, any of the tunable RF filter paths shown in the first RF filter structure 60 of FIG. 21 may be arranged in accordance with the exemplary embodiment shown in FIG. 27. The first tunable RF filter path 66 shown in FIG. 27 includes the same embodiment of the resonator R(1,1) and the same embodiment of the resonator R(1,2) described above with respect to FIG. 22. In addition, the first tunable RF filter path 66 shown in FIG. 27 includes the cross-coupling capacitive structure C(P1) and the cross-coupling capacitive structure (CN1) that form the V-bridge structure described above with respect to FIG. 22. However, the first tunable RF filter path 66 shown in FIG. 27 further includes a resonator R(1,3) and a resonator R(1,4). More specifically, the resonator R(1,3) includes an inductor 226, a capacitive structure 228, and a capacitive structure 230. The resonator R(1,4) includes an inductor 232 and a capacitive structure 234.

With regard to the resonator R(1,3), the inductor 226 is electrically connected between the capacitive structure 228 and the capacitive structure 230. More specifically, the inductor 226 has an end 236 and an end 238, which are disposed opposite to one another. The end 236 is electrically connected to the capacitive structure 228 and the end 238 is electrically connected to the capacitive structure 230. Both the capacitive structure 228 and the capacitive structure 230 are grounded. Thus, the resonator R(1,3) is a differential resonator. In this embodiment, each of the capacitive structure 228 and the capacitive structure 230 is a variable capacitive structure.

With regard to the resonator R(1,4), the inductor 232 and the capacitive structure 234 are electrically connected in parallel. More specifically, the inductor 232 has an end 240 and an end 242, which are disposed opposite to one another. The ends 240, 242 are each electrically connected to the capacitive structure 234, which is grounded. Thus, the resonator R(1,4) is a single-ended resonator.

In this embodiment, the resonator R(1,1), the resonator R(1,2), the resonator R(1,3), and the resonator R(1,4) are all weakly coupled to one another. The resonator R(1,3) and the resonator R(1,4) are weakly coupled by providing the inductor 226 and the inductor 232 such that the inductor 226 and the inductor 232 are weakly coupled. The resonators R(1,1), R(1,2), R(1,3), and R(1,4) are each operably associated with one another such that energy transfer factors between the resonators R(1,1), R(1,2), R(1,3), and R(1,4) are less than 10%. Although the resonator R(1,3) and the resonator R(1,4) are weakly coupled, the inductor 232 has a maximum lateral

width and a displacement between the inductor 226 and the inductor 232 is less than or equal to half the maximum lateral width of the inductor 232. As such, the inductor 226 and the inductor 232 are relatively close to one another. The displacement between the inductor 226 and the inductor 232 may be measured from a geometric centroid of the inductor 226 to a geometric centroid of the inductor 232. The maximum lateral width may be a maximum dimension of the inductor 232 along a plane defined by its largest winding. The weak coupling between the inductor 226 and the inductor 232 is obtained through topological techniques. For example, the inductor 226 and the inductor 232 may be fully or partially aligned, where winding(s) of the inductor 226 and winding(s) of the inductor 232 are configured to provide weak coupling through cancellation. Alternatively or additionally, a plane defining an orientation of the windings of the inductor 226 and a plane defining an orientation of the windings of the inductor 232 may be fully or partially orthogonal to one another.

In some embodiments, all of the inductors 208, 212, 226, 232 are provided such that displacements between each of the inductors 208, 212, 226, 232 are less than or equal to half the maximum lateral width of the inductor 212. Alternatively, in other embodiments, only a proper subset of the inductors 208, 212, 226, 232 has displacements that are less than or equal to half the maximum lateral width of the inductor 212. For example, while the displacement between the inductor 208 and the inductor 212 may be less than or equal to half the maximum lateral width of the inductor 212 and the displacement between the inductor 226 and the inductor 232 may be less than or equal to half the maximum lateral width of the inductor 232, the displacements from the inductor 208 and the inductor 212 to the inductor 226 and the inductor 232 may each be greater than half the maximum lateral width of the inductor 212 and half the maximum lateral width of the inductor 232.

The inductors 208, 212, 226, and 232 are magnetically coupled to the each other such that an RF signal received at the end 217 of the inductor 208 with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in filtered RF signals with the same voltage polarity being transmitted out the end 220 of the inductor 212, the end 236 of the inductor 226, and the end 240 of the inductor 232. Also, the inductors 208, 212, 226, and 232 are magnetically coupled to the each other such that an RF signal received at the end 240 of the inductor 232 with a voltage polarity (i.e., either a positive voltage polarity or a negative voltage polarity) results in filtered RF signals with the same voltage polarity being transmitted out the end 217 of the inductor 208, the end 220 of the inductor 212, and the end 236 of the inductor 226. This is indicated in FIG. 27 by the dot convention where a dot is placed at the end 217 of the inductor 208, a dot is placed at the end 220 of the inductor 212, a dot is placed at the end 236 of the inductor 226, and a dot is placed at the end 240 of the inductor 232.

The first tunable RF filter path 66 shown in FIG. 27 includes a cross-coupling capacitive structure C(P3), a cross-coupling capacitive structure C(N3), a cross-coupling capacitive structure C(P4), and a cross-coupling capacitive structure C(N4) electrically connected between the resonator R(1,2) and the resonator R(1,3). With respect to the resonator R(1,2) and the resonator R(1,3), the cross-coupling capacitive structure C(P3), the cross-coupling capacitive structure C(N3), the cross-coupling capacitive structure C(P4) and the cross-coupling capacitive structure C(N4) are arranged to have the X-bridge structure described above with respect to FIG. 23. Thus, the cross-coupling capacitive

structure C(P3) is electrically connected between the end 220 and the end 236 so as to provide a variable positive electric coupling coefficient between the resonator R(1,2) and the resonator R(1,3). The cross-coupling capacitive structure C(P3) is a variable cross-coupling capacitive structure configured to vary the variable positive electric coupling coefficient provided between the resonator R(1,2) and the resonator R(1,3). Also, the cross-coupling capacitive structure C(N3) is electrically connected between the end 220 and the end 238 so as to provide a variable negative electric coupling coefficient between the resonator R(1,2) and the resonator R(1,3). The cross-coupling capacitive structure C(N3) is a variable cross-coupling capacitive structure configured to vary the variable negative electric coupling coefficient provided between the resonator R(1,2) and the resonator R(1,3).

Additionally, the cross-coupling capacitive structure C(P4) is electrically connected between the end 222 and the end 238 so as to provide another variable positive electric coupling coefficient between the resonator R(1,2) and the resonator R(1,3). The cross-coupling capacitive structure C(P4) is a variable cross-coupling capacitive structure configured to vary the other variable positive electric coupling coefficient provided between the resonator R(1,2) and the resonator R(1,3). Finally, the cross-coupling capacitive structure C(N4) is electrically connected between the end 222 and the end 236 so as to provide another variable negative electric coupling coefficient between the resonator R(1,2) and the resonator R(1,3). The cross-coupling capacitive structure C(N4) is a variable cross-coupling capacitive structure configured to vary the other variable negative electric coupling coefficient provided between the resonator R(1,2) and the resonator R(1,3).

With respect to the resonator R(1,3) and the resonator R(1,4), the first tunable RF filter path 66 shown in FIG. 27 includes a cross-coupling capacitive structure C(P5) and a cross-coupling capacitive structure C(N5) electrically connected between the resonator R(1,3) and the resonator R(1,4). With respect to the resonator R(1,3) and the resonator R(1,4), the cross-coupling capacitive structure C(P5) and the cross-coupling capacitive structure C(N5) are arranged to have the V-bridge structure described above with respect to FIG. 22. Thus, the cross-coupling capacitive structure C(P5) is electrically connected between the end 236 and the end 240 so as to provide a variable positive electric coupling coefficient between the resonator R(1,3) and the resonator R(1,4). The cross-coupling capacitive structure C(P5) is a variable cross-coupling capacitive structure configured to vary the variable positive electric coupling coefficient provided between the resonator R(1,3) and the resonator R(1,4). Also, the cross-coupling capacitive structure C(N5) is electrically connected between the end 238 and the end 240 so as to provide a variable negative electric coupling coefficient between the resonator R(1,3) and the resonator R(1,4). The cross-coupling capacitive structure C(N5) is a variable cross-coupling capacitive structure configured to vary the variable negative electric coupling coefficient provided between the resonator R(1,3) and the resonator R(1,4).

The embodiment of first RF filter structure 60 shown in FIG. 27 also includes a cross-coupling capacitive structure C(P6), a cross-coupling capacitive structure C(N6), a cross-coupling capacitive structure C(P7), a cross-coupling capacitive structure C(N7), and a cross-coupling capacitive structure C(P8). With respect to the resonator R(1,1) and the resonator R(1,3), the cross-coupling capacitive structure C(P6) and the cross-coupling capacitive structure C(N6) are

each electrically connected between the resonator R(1,1) and the resonator R(1,3). The cross-coupling capacitive structure C(P6) is electrically connected between the end 217 and the end 236 so as to provide a variable positive electric coupling coefficient between the resonator R(1,1) and the resonator R(1,3). The cross-coupling capacitive structure C(P6) is a variable cross-coupling capacitive structure configured to vary the variable positive electric coupling coefficient provided between the resonator R(1,1) and the resonator R(1,3). Also, the cross-coupling capacitive structure C(N6) is electrically connected between the end 217 and the end 238 so as to provide a variable negative electric coupling coefficient between the resonator R(1,1) and the resonator R(1,3). The cross-coupling capacitive structure C(N6) is a variable cross-coupling capacitive structure configured to vary the variable negative electric coupling coefficient provided between the resonator R(1,1) and the resonator R(1,3).

With respect to the resonator R(1,2) and the resonator R(1,4), the cross-coupling capacitive structure C(P7) and the cross-coupling capacitive structure C(N7) are each electrically connected between the resonator R(1,2) and the resonator R(1,4). The cross-coupling capacitive structure C(P7) is electrically connected between the end 220 and the end 240 so as to provide a variable positive electric coupling coefficient between the resonator R(1,2) and the resonator R(1,4). The cross-coupling capacitive structure C(P7) is a variable cross-coupling capacitive structure configured to vary the variable positive electric coupling coefficient provided between the resonator R(1,2) and the resonator R(1,4). Also, the cross-coupling capacitive structure C(N7) is electrically connected between the end 222 and the end 240 so as to provide a variable negative electric coupling coefficient between the resonator R(1,2) and the resonator R(1,4). The cross-coupling capacitive structure C(N7) is a variable cross-coupling capacitive structure configured to vary the variable negative electric coupling coefficient provided between the resonator R(1,2) and the resonator R(1,4).

With respect to the resonator R(1,1) and the resonator R(1,4), the cross-coupling capacitive structure C(P8) is electrically connected between the resonator R(1,1) and the resonator R(1,4). The cross-coupling capacitive structure C(P8) is electrically connected between the end 217 and the end 240 so as to provide a variable positive electric coupling coefficient between the resonator R(1,1) and the resonator R(1,4). The cross-coupling capacitive structure C(P8) is a variable cross-coupling capacitive structure configured to vary the variable positive electric coupling coefficient provided between the resonator R(1,1) and the resonator R(1,4).

Furthermore, in this embodiment, a variable capacitive structure 244 is electrically connected in series between the terminal 200 and the resonator R(1,1). The variable capacitive structure 244 is configured to vary a variable impedance of the first tunable RF filter path 66 as measured into the terminal 200 in order to match a source or a load impedance at the terminal 200. In addition, a variable capacitive structure 245 is electrically connected in series between the resonator R(1,4) and the terminal 202. The variable capacitive structure 245 is configured to vary a variable impedance of the first tunable RF filter path 66 as seen into the terminal 202 in order to match a source or a load impedance at the terminal 202.

FIGS. 28A through 28D illustrate different embodiments of the first RF filter structure 60, wherein each of the embodiments has different combinations of input terminals and output terminals. The first RF filter structure 60 can have various topologies. For example, the embodiment of the first

RF filter structure 60 shown in FIG. 28A has a single input terminal IN and an integer number  $i$  of output terminals  $OUT_1$ - $OUT_i$ . As will be discussed below, the first RF filter structure 60 may define various tunable RF filter paths (e.g., the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124 shown in FIGS. 4, 8, 11, 12, and 14-20) that may be used to receive different RF signals at the input terminal IN and transmit a different filtered RF signal from each of the output terminals  $OUT_1$ - $OUT_i$ . As such, the first RF filter structure 60 shown in FIG. 28A may be specifically configured to provide Single Input Multiple Output (SIMO) operations.

With regard to the embodiment of the first RF filter structure 60 shown in FIG. 28B, the first RF filter structure 60 has an integer number  $j$  of input terminals  $IN_1$ - $IN_j$  and a single output terminal OUT. As will be discussed below, the first RF filter structure 60 may define various tunable RF filter paths (e.g., the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124 shown in FIGS. 4, 8, 11, 12, and 14-20) that may be used to receive a different RF signal at each of the input terminals  $IN_1$ - $IN_j$  and transmit different filtered RF signals from the single output terminal OUT. As such, the first RF filter structure 60 shown in FIG. 28B may be specifically configured to provide Multiple Input Single Output (MISO) operations.

With regard to the embodiment of the first RF filter structure 60 shown in FIG. 28C, the first RF filter structure 60 has a single input terminal IN and a single output terminal OUT. As will be discussed below, the first RF filter structure 60 may define various tunable RF filter paths (e.g., the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124 shown in FIGS. 4, 8, 11, 12, and 14-20) that may be used to receive different RF signals at the single input terminal IN and transmit different filtered RF signals from the output terminal OUT. As such, the first RF filter structure 60 shown in FIG. 28A may be specifically configured to provide Single Input Single Output (SISO) operations.

With regard to the embodiment of the first RF filter structure 60 shown in FIG. 28D, the first RF filter structure 60 has the input terminals  $IN_1$ - $IN_j$  and the output terminals  $OUT_1$ - $OUT_i$ . As will be discussed below, the first RF filter structure 60 may define various tunable RF filter paths (e.g., the first tunable RF filter path 66, the second tunable RF filter path 68, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable RF filter path 124 shown in FIGS. 4, 8, 11, 12, and 14-20) that may be used to receive a different RF signal at each of the input terminal  $IN_1$ - $IN_j$  and transmit a different filtered RF signal from each of the output terminals  $OUT_1$ - $OUT_i$ .

FIG. 29 illustrates another embodiment of the first RF filter structure 60. The first RF filter structure 60 shown in FIG. 29 includes one embodiment of the first tunable RF filter path 66 and one embodiment of the second tunable RF filter path 68. The first tunable RF filter path 66 includes the resonator R(1,1) and the resonator R(1,2). The resonator R(1,1) and the resonator R(1,2) are thus a first pair of weakly coupled resonators in the first tunable RF filter path 66. The second tunable RF filter path 68 includes the resonator

R(2,1) and the resonator R(2,2). The resonator R(2,1) and the resonator R(2,2) are thus a second pair of weakly coupled resonators in the second tunable RF filter path 68.

As explained in further detail below, a set S of cross-coupling capacitive structures is electrically connected between the resonator R(1,1), the resonator R(1,2), the resonator R(2,1), and the resonator R(2,2) in the first tunable RF filter path 66 and the second tunable RF filter path 68. More specifically, the set S includes a cross-coupling capacitive structure C(PM1), a cross-coupling capacitive structure C(PM2), a cross-coupling capacitive structure C(PM3), a cross-coupling capacitive structure C(PM4), a cross-coupling capacitive structure C(NM1), and a cross-coupling capacitive structure C(NM2). The set S of cross-coupling capacitive structures interconnects the resonator R(1,1), the resonator R(1,2), the resonator R(2,1), and the resonator R(2,2) so that the first RF filter structure 60 shown in FIG. 29 is a matrix (in this embodiment, a 2x2 matrix) of the resonators R. In alternative embodiments, some of the cross-coupling capacitive structures C(PM1), C(PM2), C(PM3), C(PM4), C(NM1), and C(NM2) may be omitted depending on the filter transfer function to be provided.

Unlike in the embodiment of the first RF filter structure 60 shown in FIG. 21, in this embodiment, the first tunable RF filter path 66 and the second tunable RF filter path 68 are not independent of one another. The set S of cross-coupling capacitive structures thus provides for additional tunable RF filter paths to be formed from the resonator R(1,1), the resonator R(1,2), the resonator R(2,1), and the resonator R(2,2). As discussed in further detail below, the arrangement of the first RF filter structure 60 shown in FIG. 29 can be used to realize examples of each of the embodiments of the first RF filter structure 60 shown in FIGS. 28A-28D.

The cross-coupling capacitive structure C(PM1) is electrically connected within the first tunable RF filter path 66, while the cross-coupling capacitive structure C(PM4) is electrically connected within the second tunable RF filter path 68. More specifically, the cross-coupling capacitive structure C(PM1) is electrically connected between the resonator R(1,1) and the resonator R(1,2) in the first tunable RF filter path 66. The cross-coupling capacitive structure C(PM1) is a variable cross-coupling capacitive structure configured to provide and vary a (e.g., positive or negative) electric coupling coefficient between the resonator R(1,1) and the resonator R(1,2). The cross-coupling capacitive structure C(PM4) is a variable cross-coupling capacitive structure configured to provide and vary a (e.g., positive or negative) electric coupling coefficient between the resonator R(2,1) and the resonator R(2,2) in the second tunable RF filter path 68.

To provide additional tunable RF filter paths, the cross-coupling capacitive structure C(PM2), the cross-coupling capacitive structure C(PM3), the cross-coupling capacitive structure C(NM1), and the cross-coupling capacitive structure C(NM2) are each electrically connected between the first tunable RF filter path 66 and the second tunable RF filter path 68. The cross-coupling capacitive structure C(PM2) is a variable cross-coupling capacitive structure configured to provide and vary a (e.g., positive or negative) electric coupling coefficient between the resonator R(1,2) and the resonator R(2,2). The cross-coupling capacitive structure C(PM3) is a variable cross-coupling capacitive structure configured to provide and vary a (e.g., positive or negative) electric coupling coefficient between the resonator R(1,1) and the resonator R(2,1). The cross-coupling capacitive structure C(NM1) is a variable cross-coupling capacitive structure configured to provide and vary a (e.g., positive

or negative) electric coupling coefficient between the resonator R(1,1) and the resonator R(2,2). The cross-coupling capacitive structure C(NM2) is a variable cross-coupling capacitive structure configured to provide and vary a (e.g., positive or negative) electric coupling coefficient between the resonator R(1,2) and the resonator R(2,1).

The first tunable RF filter path 66 is electrically connected between the input terminal IN<sub>1</sub> and the output terminal OUT<sub>1</sub>. In addition, the second tunable RF filter path 68 is electrically connected between an input terminal IN<sub>2</sub> and an output terminal OUT<sub>2</sub>. Accordingly, the first RF filter structure 60 shown in FIG. 29 is an embodiment of the first RF filter structure 60 shown in FIG. 28D. However, the input terminal IN<sub>2</sub> and the output terminal OUT<sub>1</sub> are optional and may be excluded in other embodiments. For example, if the input terminal IN<sub>2</sub> were not provided, but the output terminal OUT<sub>1</sub> and the output terminal OUT<sub>2</sub> were provided, the first RF filter structure 60 shown in FIG. 29 would be provided as an embodiment of the first RF filter structure 60 shown in FIG. 28A. It might, for example, provide a duplexing or a duplexing function. Furthermore, more than two input terminals or output terminals can be provided. Some examples include embodiments of the first RF filter structure 60 used for triplexing, quadplexing, herplexing, and providing FDD and carrier aggregation.

The first tunable RF filter path 66 still provides a path between the input terminal IN<sub>1</sub> and the output terminal OUT<sub>1</sub>. However, assuming that the input terminal IN<sub>2</sub> is not provided for SIMO operation, the cross-coupling capacitive structure C(NM1) is electrically connected between the first tunable RF filter path 66 and the second tunable RF filter path 68 to define a first additional tunable RF filter path between the input terminal IN<sub>1</sub> and the output terminal OUT<sub>2</sub>. The first additional tunable RF filter path is thus provided by a portion of the first tunable RF filter path 66 and a portion of the second tunable RF filter path 68. More specifically, the first additional tunable RF filter path includes the resonator R(1,1) and the resonator R(2,2). The first additional tunable RF filter path also includes the cross-coupling capacitive structure C(NM1) that is electrically connected between the resonator R(1,1) and the resonator R(1,2). A second additional tunable RF filter path, a third additional tunable RF filter path, a fourth additional tunable RF filter path, and a fifth additional tunable RF filter path are also defined from the input terminal IN<sub>1</sub> to the output terminal OUT<sub>2</sub>. The second additional tunable RF filter path includes the resonator R(1,1), the cross-coupling capacitive structure C(PM1), the resonator R(1,2), the cross-coupling capacitive C(PM2), and the resonator R(2,2). Additionally, the third additional tunable RF filter path includes the resonator R(1,1), the cross-coupling capacitive structure C(PM3), the resonator R(2,1), the cross-coupling capacitive C(PM4), and the resonator R(2,2). The fourth additional tunable RF filter path includes the resonator R(1,1), the cross-coupling capacitive structure C(PM1), the resonator R(1,2), the cross-coupling capacitive C(NM2), the resonator R(2,1), the cross-coupling capacitive structure C(PM4), and the resonator R(2,2). Finally, the fifth additional tunable RF filter path includes the resonator R(1,1), the cross-coupling capacitive structure C(PM3), the resonator R(2,1), the cross-coupling capacitive C(NM2), the resonator R(1,2), the cross-coupling capacitive structure C(PM2), and the resonator R(2,2).

If the output terminal OUT<sub>1</sub> were not provided, but the input terminal IN<sub>1</sub> and the input terminal IN<sub>2</sub> were provided, the first RF filter structure 60 shown in FIG. 29 would be provided as an embodiment of the first RF filter structure 60

shown in FIG. 28B. In this case, the second tunable RF filter path 68 still provides a path between the input terminal  $IN_2$  and the output terminal  $OUT_2$ . However, assuming that the output terminal  $OUT_1$  is not provided for MISO operation, the first additional tunable RF filter path, the second additional tunable RF filter path, the third additional tunable RF filter path, the fourth additional tunable RF filter path, and the fifth additional tunable RF filter path would provide the paths from the input terminal  $IN_1$  to the output terminal  $OUT_2$ .

Finally, if the input terminal  $IN_2$  and the output terminal  $OUT_2$  were not provided, the first RF filter structure 60 shown in FIG. 29 would be provided as an embodiment of the first RF filter structure 60 shown in FIG. 28C. In this case, the second tunable RF filter path 68 still provides a path between the input terminal  $IN_2$  and the output terminal  $OUT_2$ . However, assuming that the output terminal  $IN_1$  is not provided for MISO operation, the first additional tunable RF filter path, the second additional tunable RF filter path, the third additional tunable RF filter path, the fourth additional tunable RF filter path, and the fifth additional tunable RF filter path would provide the paths from the input terminal  $IN_1$  to the output terminal  $OUT_2$ . This may constitute a SISO filter implemented with an array to allow for a large number of signal paths and thus create one or more notches in the transfer function.

With regard to the resonators  $R(1,1)$ ,  $R(1,2)$ ,  $R(2,1)$ ,  $R(2,2)$  shown in FIG. 29, the resonators  $R(1,1)$ ,  $R(1,2)$ ,  $R(2,1)$ ,  $R(2,2)$  may each be single-ended resonators, differential resonators, or different combinations of single-ended resonators and differential resonators. The resonator  $R(1,1)$  and the resonator  $R(1,2)$  in the first tunable RF filter path 66 may each be provided in accordance with any of the embodiments of the resonator  $R(1,1)$  and the resonator  $R(1,2)$  described above with respect to FIGS. 22-27. For example, the resonator  $R(1,1)$  may include the inductor 208 (see FIG. 24) and the capacitive structure 210 (see FIG. 24). The resonator  $R(1,2)$  may include the inductor 212 and the capacitive structure 214 (see FIG. 24). The resonator  $R(2,1)$  may include an inductor (like the inductor 208 in FIG. 24) and a capacitive structure (like the capacitive structure 210 shown in FIG. 24). The resonator  $R(2,2)$  may include an inductor (like the inductor 212 in FIG. 24) and a capacitive structure (like the capacitive structure 214 shown in FIG. 24).

Additionally, one or more of the resonators  $R(1,1)$ ,  $R(1,2)$  in the first tunable RF filter path 66 and one or more of the resonators  $R(2,1)$ ,  $R(2,2)$  in the second tunable RF filter path 68 may be weakly coupled. Thus, the resonators  $R(1,1)$ ,  $R(1,2)$ ,  $R(2,1)$ ,  $R(2,2)$  may be operably associated with one another such that an energy transfer factor between each of the resonators  $R(1,1)$ ,  $R(1,2)$ ,  $R(2,1)$ ,  $R(2,2)$  is less than 10%. Alternatively, the energy transfer factor between only a subset of the resonators  $R(1,1)$ ,  $R(1,2)$ ,  $R(2,1)$ ,  $R(2,2)$  is less than 10%. In addition, in at least some embodiments, not all of the resonators  $R(1,1)$ ,  $R(1,2)$ ,  $R(2,1)$ ,  $R(2,2)$  are weakly coupled to one another.

In this embodiment, the inductor 208 (see FIG. 24) of the resonator  $R(1,1)$ , the inductor 212 (see FIG. 24) of the resonator  $R(1,2)$ , the inductor of the resonator  $R(2,1)$ , and the inductor of the resonator  $R(2,2)$  may all be weakly coupled to one another. In some embodiments, displacements between the inductor 208 (see FIG. 24) of the resonator  $R(1,1)$ , the inductor 212 (see FIG. 24) of the resonator  $R(1,2)$ , the inductor of the resonator  $R(2,1)$ , and the inductor of the resonator  $R(2,2)$  may all be less than or equal to half the maximum lateral width of the inductor 212.

Alternatively, in other embodiments, only a proper subset of the inductor 208 (see FIG. 24) of the resonator  $R(1,1)$ , the inductor 212 (see FIG. 24) of the resonator  $R(1,2)$ , the inductor of the resonator  $R(2,1)$ , and the inductor of the resonator  $R(2,2)$  may have displacements that are less than or equal to half the maximum lateral width of the inductor 212.

FIG. 30 illustrates yet another embodiment of the first RF filter structure 60. The first RF filter structure 60 includes the resonators  $R$  described above with respect to FIG. 21. The resonators  $R$  of the first RF filter structure 60 shown in FIG. 30 are arranged as a two-dimensional matrix of the resonators  $R$ . In this embodiment, the first RF filter structure 60 includes an embodiment of the first tunable RF filter path 66, an embodiment of the second tunable RF filter path 68, an embodiment of the third tunable RF filter path 110, and an embodiment of the fourth tunable RF filter path 112. Thus, the integer  $M$  for the first RF filter structure 60 shown in FIG. 30 is four (4) or greater. Additionally, the integer  $N$  for the first RF filter structure 60 shown in FIG. 30 is 3 or greater. Note that in alternative embodiments, the integer  $M$  may be two (2) or greater and the integer  $N$  may be two (2) or greater. It should be noted that in alternative embodiments the number of resonators  $R$  in each row and column may be the same or different.

In the embodiment of the first RF filter structure 60 shown in FIG. 30, the first tunable RF filter path 66 includes the resonator  $R(1,1)$ , the resonator  $R(1,2)$ , and one or more additional resonators  $R$ , such as the resonator  $R(1,N)$ , since the integer  $N$  is 3 or greater. All of the weakly coupled resonators  $R(1,1)$  through  $R(1,N)$  are weakly coupled to one another. Furthermore, the first tunable RF filter path 66 is electrically connected between a terminal  $TU1$  and a terminal  $TANT1$ . With regard to the second tunable RF filter path 68, the second tunable RF filter path 68 includes the resonator  $R(2,1)$ , the resonator  $R(2,2)$ , and one or more additional resonators  $R$ , such as the resonator  $R(2,N)$ , since the integer  $N$  is 3 or greater. All of the weakly coupled resonators  $R(2,1)$  through  $R(2,N)$  are weakly coupled to one another. Furthermore, the second tunable RF filter path 68 is electrically connected between a terminal  $TU2$  and a terminal  $TANT2$ .

With regard to the third tunable RF filter path 110, the third tunable RF filter path 110 includes a resonator  $R(3,1)$ , a resonator  $R(3,2)$ , and one or more additional resonators  $R$ , such as a resonator  $R(3,N)$ , since the integer  $N$  is 3 or greater. All of the weakly coupled resonators  $R(3,1)$  through  $R(3,N)$  are weakly coupled to one another. Alternatively, only a proper subset of them may be weakly coupled to one another. Furthermore, the third tunable RF filter path 110 is electrically connected between a terminal  $TU3$  and a terminal  $TANT3$ . With regard to the fourth tunable RF filter path 112, the fourth tunable RF filter path 112 includes the resonator  $R(M,1)$ , the resonator  $R(M,2)$ , and one or more additional resonators  $R$ , such as the resonator  $R(M,N)$ , since the integer  $N$  is 3 or greater. All of the weakly coupled resonators  $R(M,1)$  through  $R(M,N)$  are weakly coupled to one another. Alternatively, only a proper subset of them may be weakly coupled to one another. Furthermore, the fourth tunable RF filter path 112 is electrically connected between a terminal  $TU4$  and a terminal  $TANT4$ .

The first tunable RF filter path 66 is configured to receive RF signals and output filtered RF signals. It should be noted that the first RF filter structure 60 may include any number of tunable RF filter paths, such as, for example, the third tunable RF filter path 110, the fourth tunable RF filter path 112, the fifth tunable RF filter path 122, and the sixth tunable

RF filter path **124**, described above with respect to FIGS. **11-14**. Each of the resonators **R** may be a tunable resonator, which allows for a resonant frequency of each of the resonators to be varied to along a frequency range. In alternative embodiments, only a proper subset of the resonators **R** may be tunable. In still another embodiment, all of the resonators **R** are not tunable, but rather have a fixed transfer function.

In some embodiments, all of the resonators **R** in the first RF filter structure **60** shown in FIG. **30** are weakly coupled to one another. Thus, the resonators **R** may all be operably associated with one another such that energy transfer factors between the resonators **R** are less than 10%. Alternatively, the energy transfer factor is less than 10% only among a proper subset of the resonators **R**. In other embodiments, only the resonators **R** in adjacent tunable RF filter paths **66**, **68**, **110**, **112** are weakly coupled to one another. For example, all the resonators **R**(**1,1**) through **R**(**1,N**) may be weakly coupled to all the resonators **R**(**2,1**) through **R**(**2,N**). In still other embodiments, only subsets of adjacent resonators **R** may be weakly coupled to each other. For example, the resonators **R**(**1,1**), **R**(**1,2**) may be weakly coupled to the resonators **R**(**2,1**), **R**(**2,2**), while the resonators **R**(**3,1**), **R**(**3,2**) may be weakly coupled to the resonators **R**(**M,1**), **R**(**M,2**). These and other combinations would be apparent to one of ordinary skill in the art in light of this disclosure.

Sets **S**(**1**), **S**(**2**), **S**(**3**), **S**(**4**), **S**(**5**), and **S**(**6**) of cross-coupled capacitive structures are electrically connected between the resonators **R**. Each of the sets **S**(**1**), **S**(**2**), **S**(**3**), **S**(**4**), **S**(**5**), and **S**(**6**) is arranged like the set **S** of cross-coupled capacitive structures described above with respect to FIG. **29**. For example, in one particular exemplary embodiment (e.g., when **M**=4 and **N**=3), the set **S**(**1**) of cross-coupled capacitive structures is electrically connected between the resonators **R**(**1,1**), **R**(**1,2**) in the first tunable RF filter path **66** and the resonators **R**(**2,1**), **R**(**2,2**) in the second tunable RF filter path **68**. The set **S**(**2**) of cross-coupled capacitive structures is electrically connected between the resonators **R**(**1,2**), **R**(**1,N**) in the first tunable RF filter path **66** and the resonators **R**(**2,2**), **R**(**2,N**) in the second tunable RF filter path **68**. The set **S**(**3**) of cross-coupled capacitive structures is electrically connected between the resonators **R**(**2,1**), **R**(**2,2**) in the second tunable RF filter path **68** and the resonators **R**(**3,1**), **R**(**3,2**) in the third tunable RF filter path **110**. The set **S**(**4**) of cross-coupled capacitive structures is electrically connected between the resonators **R**(**2,2**), **R**(**2,N**) in the second tunable RF filter path **68** and the resonators **R**(**3,2**), **R**(**3,N**) in the third tunable RF filter path **110**. The set **S**(**5**) of cross-coupled capacitive structures is electrically connected between the resonators **R**(**3,1**), **R**(**3,2**) in the third tunable RF filter path **110** and the resonators **R**(**M,1**), **R**(**M,2**) in the fourth tunable RF filter path **112**. Finally, the set **S**(**6**) of cross-coupled capacitive structures is electrically connected between the resonators **R**(**3,2**), **R**(**3,N**) in the third tunable RF filter path **110** and the resonators **R**(**M,2**), **R**(**M,N**) in the fourth tunable RF filter path **112**. Note that some cross-coupled capacitive structures in the sets **S**(**1**), **S**(**2**), **S**(**3**), **S**(**4**), **S**(**5**), and **S**(**6**) of cross-coupled capacitive structures for the resonators **R** in adjacent columns or in adjacent ones of the tunable RF filter paths **66**, **68**, **110**, **112** overlap. This is because in the matrix of the resonators **R**, each of the resonators **R** is adjacent to multiple other ones of the resonators **R**. In another embodiment, the sets **S**(**1**), **S**(**2**), **S**(**3**), **S**(**4**), **S**(**5**), and **S**(**6**) of cross-coupled capacitive structures may be connected between non-adjacent resonators **R**.

For example, there may be cross-coupled capacitive structures between resonators **R** that are more than one column or row apart.

FIG. **31** illustrates the embodiment of the first RF filter structure **60** shown in FIG. **30** electrically connected to the first RF antenna **16**, the second RF antenna **32**, a third RF antenna **246**, and a fourth RF antenna **247**. More specifically, the first tunable RF filter path **66** is electrically connected to the first RF antenna **16** at the terminal **TANT1**. The second tunable RF filter path **68** is electrically connected to the second RF antenna **32** at the terminal **TANT2**. The third tunable RF filter path **110** is electrically connected to the third RF antenna **246** at the terminal **TANT3**. The fourth tunable RF filter path **112** is electrically connected to the fourth RF antenna **247** at the terminal **TANT4**. With the sets **S**(**1**), **S**(**2**), **S**(**3**), **S**(**4**), **S**(**5**), and **S**(**6**) of cross-coupled capacitive structures, the first RF filter structure **60** shown in FIG. **31** forms an interconnected two-dimensional matrix of the resonators **R**. Thus, in addition to the first tunable RF filter path **66**, the second tunable RF filter path **68**, the third tunable RF filter path **110**, and the fourth tunable RF filter path **112**, the sets **S**(**1**), **S**(**2**), **S**(**3**), **S**(**4**), **S**(**5**), and **S**(**6**) of cross-coupled capacitive structures provide a multitude of additional tunable RF filter paths between the terminals **TU1**, **TU2**, **TU3**, **TU4** and the terminals **TANT1**, **TANT2**, **TANT3**, **TANT4**. It should be noted that in alternative embodiments, the terminals **TANT1**, **TANT2**, **TANT3**, **TANT4** may not be connected to antennas. Some antennas may be omitted depending on the functionality being realized.

By tuning the sets **S**(**1**), **S**(**2**), **S**(**3**), **S**(**4**), **S**(**5**), and **S**(**6**), the first RF filter structure **60** shown in FIG. **31** can be tuned so that any combination of the resonators **R** is selectable for the propagation of RF signals. More specifically, the first RF filter structure **60** shown in FIG. **31** is tunable to route RF receive signals from any combination of the terminals **TANT1**, **TANT2**, **TANT3**, **TANT4** to any combination of the terminals **TU1**, **TU2**, **TU3**, **TU4**. Additionally, the first RF filter structure **60** shown in FIG. **31** is tunable to route RF transmission signals from any combination of the terminals **TU1**, **TU2**, **TU3**, **TU4** to the terminals **TANT1**, **TANT2**, **TANT3**, **TANT4**. Accordingly, the first RF filter structure **60** can be configured to implement various MIMO, SIMO, MISO, and SISO operations.

FIG. **32** illustrates the first RF filter structure **60** shown in FIGS. **30** and **31** with examples of additional tunable RF filter paths **248**, **250** highlighted. It should be noted, however, that there are a vast number of additional combinations of the resonators **R** that may be selected to provide tunable RF filter paths (e.g., the first tunable RF filter path **66**, the second tunable RF filter path **68**, the third tunable RF filter path **110**, the fourth tunable RF filter path **112**, the additional tunable RF filter path **248**, and the additional tunable RF filter path **250**) between the terminals **TU1**, **TU2**, **TU3**, **TU4** and the terminals **TANT1**, **TANT2**, **TANT3**, **TANT4**. An explicit description of all of the various combinations of the resonators **R** that may be implemented with the first RF filter structure **60** shown in FIGS. **30-32** is simply impractical given the high number of possible combinations. Along with the previous descriptions, the additional tunable RF filter paths **248**, **250** are highlighted in FIG. **32** simply to give examples of the basic concepts. However, the combinations provided for the additional tunable RF filter paths **248**, **250** are in no way limiting, as any combination of the resonators **R** may be selected to route RF signals between the terminals **TU1**, **TU2**, **TU3**, **TU4** and the terminals **TANT1**, **TANT2**, **TANT3**, **TANT4**. Any number of functions, such as signal

## 51

combining, splitting, multiplexing, and demultiplexing, with various filtering profiles for each, may be realized.

With regard to the additional tunable RF filter paths **248**, **250** highlighted in FIG. **32**, the additional tunable RF filter paths **248**, **250** may be used during MIMO, SIMO, MISO, and SISO operations. More specifically, the additional tunable RF filter path **248** connects the terminal TANT1 to the terminal TU2. The additional tunable RF filter path **250** connects the terminal TANT3 to the terminal TU2. As such, the first RF filter structure **60** may be tuned so that the additional tunable RF filter path **248** and the additional tunable RF filter path **250** are selected in a MISO operation from the terminal TANT1 and the terminal TANT3 to the terminal TU2. The additional tunable RF filter paths **248**, **250** may also be used in SIMO operations. For example, the first RF filter structure **60** may be tuned so that the first tunable RF filter path **66** and the additional tunable RF filter path **248** are selected in a SIMO operation from the terminal TU2 to the terminal TANT1. The additional tunable RF filter paths **248**, **250** can also be used in SISO operations from the terminal TANT1 to the terminal TU2 or from the terminal TANT3 to the terminal TU2. Finally, the additional tunable RF filter paths **248**, **250** may also be used in SIMO operations. For instance, the first RF filter structure **60** may be tuned so that the first tunable RF filter path **66** and the additional tunable RF filter path **250** are selected in a SIMO operation from the terminal TANT1 to the terminal TU1 and from the terminal TANT3 to the terminal TU2.

In some applications involving the first RF filter structure **60** in FIGS. **30-32**, MISO and SIMO operations can be used in conjunction with wideband antenna cables or fiber for transmitting RF signals in multiple RF communication frequency bands. Specific communication frequency bands can be processed by certain dedicated RF filtering paths in the first RF filter structure **60**. For example, different RF signals may be injected from a wideband antenna and then propagated along different dedicated tunable RF filter paths in the first RF filter structure **60** to the terminals TU1, TU2, TU3, TU4. These dedicated tunable RF filter paths can be configured to have a transfer function that is specifically designed to handle these RF signals. Furthermore, the first RF filter structure **60** shown in FIGS. **30-32** is configured to tune a transfer function of any of the specific tunable RF filter paths (e.g., the first tunable RF filter path **66**, the second tunable RF filter path **68**, the third tunable RF filter path **110**, the fourth tunable RF filter path **112**, the additional tunable RF filter path **248**, and the additional tunable RF filter path **250**) in the first RF filter structure **60** by tuning resonators R that are not in the specific tunable RF filter path being used to route RF signals. This can help reduce out-of-band noise and reduce insertion losses. It can also improve isolation and out-of-band attenuation.

FIG. **33** illustrates yet another embodiment of the first RF filter structure **60**. The first RF filter structure **60** includes the resonators R and is arranged as a two-dimensional matrix of the resonators R, where N is equal to four (4) and M is equal to three (3). In this embodiment, the first RF filter structure **60** includes an embodiment of the first tunable RF filter path **66**, an embodiment of the second tunable RF filter path **68**, and an embodiment of the third tunable RF filter path **110**. It should be noted that in alternative embodiments, the number of resonators R in each row and column may be the same or different.

In the embodiment of the first RF filter structure **60** shown in FIG. **33**, the first tunable RF filter path **66** includes the resonator R(1,1), the resonator R(1,2), the resonator R(1,3), and the resonator R(1,4). Furthermore, the first tunable RF

## 52

filter path **66** is electrically connected between the terminal TU1 and the terminal TANT1. With regard to the second tunable RF filter path **68**, the second tunable RF filter path **68** includes the resonator R(2,1), the resonator R(2,2), a resonator R(2,3), and a resonator R(2,4). Furthermore, the second tunable RF filter path **68** is electrically connected between the terminal TU2 and the terminal TANT2. With regard to the third tunable RF filter path **110**, the third tunable RF filter path **110** includes the resonator R(3,1), the resonator R(3,2), a resonator R(3,3), and a resonator R(3,4). Furthermore, the third tunable RF filter path **110** is electrically connected between the terminal TU3 and the terminal TANT3.

In this embodiment, the resonators R in a subset **252** of the resonators R(1,1), R(1,2) in the first tunable RF filter path **66** are weakly coupled to one another. A cross-coupling capacitive structure CS1 is electrically connected between the resonators R(1,1), R(1,2). The cross-coupling capacitive structure CS1 is a variable cross-coupling capacitive structure configured to vary a variable electric coupling coefficient between the resonators R(1,1), R(1,2). A subset **254** of the resonators R(1,3), and R(1,4) in the second tunable RF filter path **68** is also weakly coupled to each other. A cross-coupling capacitive structure CS2 is electrically connected between the resonators R(1,3), R(1,4). The cross-coupling capacitive structure CS2 is a variable cross-coupling capacitive structure configured to vary a variable electric coupling coefficient between the resonators R(1,3), R(1,4).

As shown in FIG. **33**, a unidirectional coupling stage **256** is electrically connected within the first tunable RF filter path **66**. The unidirectional coupling stage **256** defines an amplifier gain and is configured to provide amplification within the first tunable RF filter path **66** in accordance with the amplifier gain. In some embodiments, the amplifier gain of the unidirectional coupling stage **256** is a variable amplifier gain. In this embodiment, the unidirectional coupling stage **256** is electrically connected between the resonator R(1,2) and the resonator R(1,3). The variable amplifier gain can thus control a variable electric coupling coefficient between the resonator R(1,2) in the subset **252** and the resonator R(1,3) in the subset **254**. Since the unidirectional coupling stage **256** is an active semiconductor component, the unidirectional coupling stage **256** is unidirectional and thus only allows signal propagations from an input terminal IA of the unidirectional coupling stage **256** to an output terminal OA of the unidirectional coupling stage **256**. Thus, the resonator R(1,2) in the subset **252** is unidirectionally mutual electrically coupled to the resonator R(1,3) in the subset **254**.

Note that the resonators R(1,3), R(1,4) in the subset **254** are not electrically connected to the second tunable RF filter path **68** and the third tunable RF filter path **110**. As such, the unidirectional coupling stage **256** thus results in a portion of the first tunable RF filter path **66** with the subset **254** of the resonators R(1,3), R(1,4) to be unidirectional. Consequently, signal flow can be to the terminal TANT1 but not from the terminal TANT1. Since the unidirectional coupling stage **256** is unidirectional, the variable amplifier gain (and thus the variable electric coupling coefficient between the resonator R(1,2) and the resonator R(1,3)) may be controlled using feed-forward control techniques and/or feedback control techniques.

Next, the resonators R in a subset **258** of the resonators R(2,1), R(2,2), R(3,1), and R(3,2) in the second tunable RF filter path **68** and in the third tunable RF filter path **110** are weakly coupled to one another. An unidirectional coupling

53

stage 260 is electrically connected between the first tunable RF filter path 66 and the second tunable RF filter path 68. More specifically, the unidirectional coupling stage 260 is electrically connected between the resonator R(1,1) and the resonator R(2,1). The unidirectional coupling stage 260 defines an amplifier gain and is configured to provide amplification in accordance with the amplifier gain. In some embodiments, the amplifier gain of the unidirectional coupling stage 260 is a variable amplifier gain. The variable amplifier gain thus can control a variable electric coupling coefficient between the resonator R(1,1) in the subset 252 and the resonator R(2,1) in the subset 258. A cross-coupling capacitive structure CS3 is electrically connected between the resonator R(1,2) and the resonator R(2,2). The cross-coupling capacitive structure CS3 is a variable cross-coupling capacitive structure configured to vary a variable electric coupling coefficient between the resonators R(1,2), R(2,2).

To interconnect the resonators R(2,1), R(2,2), R(3,1), and R(3,2), a set S(A) of cross-coupling capacitive structures is electrically connected between the resonators R(2,1), R(2,2), R(3,1), and R(3,2) in the subset 258. The set S(A) of cross-coupling capacitive structures is arranged like the set S of cross-coupling capacitive structures described above with respect to FIG. 29. Additionally, the resonators R in a subset 262 of the resonators R(2,3), R(2,4), R(3,3), and R(3,4) in the second tunable RF filter path 68 and in the third tunable RF filter path 110 are weakly coupled to one another. A set S(B) of cross-coupling capacitive structures is electrically connected between the resonators R(2,3), R(2,4), R(3,3), and R(3,4) in the subset 262. The set S(B) of cross-coupling capacitive structures is arranged like the set S of cross-coupling capacitive structures described above with respect to FIG. 29.

To interconnect the subset 258 and the subset 262, the first RF filter structure 60 shown in FIG. 33 includes a cross-coupling capacitive structure CS4 and a unidirectional coupling stage 264. The cross-coupling capacitive structure CS4 is electrically connected between the resonators R(2,2), R(2,3). The cross-coupling capacitive structure CS4 is a variable cross-coupling capacitive structure configured to vary a variable electric coupling coefficient between the resonators R(2,2), R(2,3). The unidirectional coupling stage 264 is electrically connected within the third tunable RF filter path 110. In this embodiment, the unidirectional coupling stage 264 is electrically connected between the resonator R(3,3) and the resonator R(3,2). The unidirectional coupling stage 264 defines an amplifier gain and is configured to provide amplification within the third tunable RF filter path 110 in accordance with the amplifier gain. In some embodiments, the amplifier gain of the unidirectional coupling stage 264 is a variable amplifier gain. The variable amplifier gain can thus control a variable electric coupling coefficient between the resonator R(3,3) in the subset 262 and the resonator R(3,2) in the subset 258. Since the unidirectional coupling stage 264 is an active semiconductor component, the unidirectional coupling stage 264 is unidirectional and thus only allows signal propagations from an input terminal IB of the unidirectional coupling stage 264 to an output terminal OB of the unidirectional coupling stage 264. Thus, the resonator R(3,3) in the subset 262 is unidirectionally mutual electrically coupled to the resonator R(3,2) in the subset 258. Consequently, the third tunable RF filter path 110 shown in FIG. 33 is unidirectional if the signal flow is between the terminal TANT3 and the terminal TU3 though the third tunable RF filter path 110. As such signal flow between the terminal TANT3 and the terminal TU3 is

54

provided only through the third tunable RF filter path 110, signal flow can only be from the terminal TANT3 to the terminal TU3, and not vice versa. In other cases, an additional tunable RF signal path (e.g., the additional RF terminal tunable RF signal path that includes the resonators R(3,1), R(2,2), R(2,3) and R(3,4)) can be tuned to provide bidirectional signal flow between the terminal TU3 and the terminal TANT3 through the cross-coupling capacitive structure CS4. The unidirectional coupling stages 256, 260, 264 may be active devices, such as amplifiers, diodes, transistors, networks of transistors, buffer stages, attenuation stages, and the like. The unidirectional coupling stages 256, 260, 264 can have gains higher than one (1), lower than one (1), or equal to one (1). Additionally, the unidirectional coupling stages 256, 260, 264 may be passive devices. The unidirectional coupling stages 256, 260, 264 may not be entirely or ideally unilateral, but may have some finite reverse coupling. In this case, the unidirectional coupling stages 256, 260, 264 may be predominately unilateral. One example in which the unidirectional coupling stages 256, 260, 264 may be used for multi-resonator applications and may improve isolation between certain parts, such as transmission ports and receive ports of a duplexer.

FIG. 34 illustrates yet another embodiment of the first RF filter structure 60. The first RF filter structure 60 shown in FIG. 34 is integrated into an IC package 266. The first RF filter structure 60 shown in FIG. 34 includes the resonators R and is arranged as a two-dimensional matrix of the resonators R, where N is equal to three (3) and M is equal to two (2). It should be noted that in alternative embodiments the number of resonators R in each row and column may be the same or different.

In this embodiment, the first RF filter structure 60 includes an embodiment of the first tunable RF filter path 66 and an embodiment of the second tunable RF filter path 68. The first tunable RF filter path 66 includes the resonator R(1,1), the resonator R(1,2), and the resonator R(1,3). The second tunable RF filter path 68 includes the resonator R(2,1), the resonator R(2,2), and the resonator R(2,3). A set S(X) of cross-coupling capacitive structures is electrically connected between the resonators R(1,1), R(1,2), R(2,1), and R(2,2). The set S(X) of cross-coupling capacitive structures is arranged like the set S of cross-coupling capacitive structures described above with respect to FIG. 29. A set S(Y) of cross-coupling capacitive structures is electrically connected between the resonators R(1,2), R(1,3), R(2,2), and R(2,3). The set S(Y) of cross-coupling capacitive structures is also arranged like the set S of cross-coupling capacitive structures described above with respect to FIG. 29.

As shown in FIG. 34, the IC package 266 houses a package substrate 268, a semiconductor die 270, and a semiconductor die 272. The semiconductor die 270 and the semiconductor die 272 are mounted on the package substrate 268. In this embodiment, the resonators R of the first RF filter structure 60 are formed by the package substrate 268. The set S(X) of cross-coupling capacitive structures is formed by the semiconductor die 270. On the other hand, the set S(Y) of cross-coupling capacitive structures is formed by the semiconductor die 272. Thus, the set S(X) of cross-coupling capacitive structures and the set S(Y) of cross-coupling capacitive structures are formed on multiple and separate semiconductor dies 270, 272. Using the multiple and separate semiconductor dies 270, 272 may be helpful in order to increase isolation. The multiple and separate semiconductor dies 270, 272 may have less area than the semi-

55

conductor die **268** shown in FIG. **34**. As such, the embodiment shown in FIG. **35** may consume less die area.

FIG. **35** illustrates another embodiment of an IC package **266'** that houses the same embodiment of the first RF filter structure **60** described above with regard to FIG. **34**. The IC package **266'** is the same as the IC package **266** shown in FIG. **34**, except that the IC package **266'** only has a single semiconductor die **274**. In this embodiment, both the set S(X) of cross-coupling capacitive structures and the set S(Y) of cross-coupling capacitive structures are formed by the semiconductor die **272**. Thus, the IC package **266'** allows for a more compact arrangement than the IC package **266**.

FIG. **36** illustrates yet another embodiment of the first RF filter structure **60**. In this embodiment, the first RF filter structure **60** is arranged as a three-dimensional matrix of resonators **R1**, **R2**, **R3**. More specifically, a two-dimensional matrix of the resonators **R1** is provided on a plane k, a two-dimensional array of the resonators **R2** is provided on a plane m, and a two-dimensional array of the resonators **R3** is provided on a plane n. Cross-coupling capacitive structures **CC** are electrically connected between the resonators **R1**, **R2**, **R3** that are adjacent to one another in the same plane k,m,n and in the different planes k,m,n. The three-dimensional matrix of resonators **R1**, **R2**, **R3** thus allows for more resonators to be cross-coupled to one another. This allows for the first RF filter structure **60** to provide greater numbers of tunable RF filter paths and allows for the first RF filter structure **60** to be tuned more accurately.

In general, having more tunable RF filter paths allows for the synthesis of a more complex transfer function with multiple notches for better blocker rejection. The number of resonators **R1**, **R2**, **R3** in each of the planes k, n, m may be different or the same. The three-dimensional matrix of resonators can be used in MIMO, SIMO, MISO, and SISO applications.

FIG. **37** shows the RF communications circuitry **54** according to one embodiment of the RF communications circuitry **54**. The RF communications circuitry **54** illustrated in FIG. **37** is similar to the RF communications circuitry **54** illustrated in FIG. **4**, except in the RF communications circuitry **54** illustrated in FIG. **37**, the RF receive circuitry **62**, the first tunable RF filter path **66**, and the second tunable RF filter path **68** are omitted. Additionally, the RF front-end circuitry **58** further includes an antenna matching filter **600**; the first RF filter structure **60** includes a first tunable RF filter **602**, which is a first tunable RF transmit filter **604** in one embodiment of the first tunable RF filter **602**; and the RF system control circuitry **56** includes a measurement-based RF spectrum profile **606**.

In one embodiment of the first RF filter structure **60**, the RF filter structure **60** includes the pair of weakly coupled resonators **R(1,1)**, **R(1,2)** (FIG. **21**). Additionally, the first RF filter structure **60** includes the first connection node **70** and the first common connection node **74**. The first tunable RF filter **602** is directly coupled between the first connection node **70** and the first common connection node **74**. The antenna matching filter **600** is coupled between the first common connection node **74** and the first RF antenna **16**, such that the first tunable RF filter **602** is coupled to the first RF antenna **16** via the antenna matching filter **600**. In an alternate embodiment of the RF front-end circuitry **58**, the antenna matching filter **600** is omitted, such that the first tunable RF filter **602** is directly coupled to the first RF antenna **16**. In another embodiment of the RF front-end circuitry **58**, the antenna matching filter **600** includes both filtering circuitry and switching circuitry. In a further

56

embodiment of the RF front-end circuitry **58**, the antenna matching filter **600** is replaced with switching circuitry (not shown).

The RF system control circuitry **56** provides a first filter control signal **FCS1** and a first filter reconfiguration signal **FCS1R** to the first tunable RF filter **602** in general, and to the first tunable RF transmit filter **604** in particular. In general, the RF communications circuitry **54** includes control circuitry **56**, **98** (FIG. **39**), which may be either the RF system control circuitry **56** or the RF front-end control circuitry **98** (FIG. **39**), that provides the first filter control signal **FCS1** and the first filter reconfiguration signal **FCS1R**. In one embodiment of the first filter control signal **FCS1**, the first filter control signal **FCS1** is based on the measurement-based RF spectrum profile **606**. In one embodiment of the first filter reconfiguration signal **FCS1R**, the first filter reconfiguration signal **FCS1R** is based on the measurement-based RF spectrum profile **606**. In an alternate embodiment of the RF communications circuitry **54**, the first filter reconfiguration signal **FCS1R** is omitted.

The RF system control circuitry **56** provides the first transmit signal **TX1** to the RF transmit circuitry **64**, which receives and processes the first transmit signal **TX1** to provide the first upstream RF transmit signal **TU1** to the first tunable RF filter **602** via the first connection node **70**. The first tunable RF transmit filter **604** receives and filters the first upstream RF transmit signal **TU1** to provide the first filtered RF transmit signal **TF1** to the antenna matching filter **600** via the first common connection node **74**.

In general, in one embodiment of the first tunable RF filter **602**, the first tunable RF filter **602** receives and filters an upstream RF signal to provide a first filtered RF signal, such that a center frequency, which is a tunable center frequency **626** (FIG. **40B**) of the first tunable RF filter **602**, is based on the first filter control signal **FCS1**. In one embodiment of the first tunable RF filter **602**, the first tunable RF filter **602** is a reconfigurable tunable RF filter **602**, such that a shape of a transfer function of the first tunable RF filter **602** is reconfigurable. As such, in one embodiment of the first tunable RF filter **602**, a configuration of the first tunable RF filter **602** is based on the first filter reconfiguration signal **FCS1R**.

FIG. **38** shows the RF communications circuitry **54** according to an alternate embodiment of the RF communications circuitry **54**. The RF communications circuitry **54** illustrated in FIG. **38** is similar to the RF communications circuitry **54** illustrated in FIG. **37**, except in the RF communications circuitry **54** illustrated in FIG. **38**; the RF transmit circuitry **64**, the antenna matching filter **600**, and the first tunable RF transmit filter **604** are omitted; and the first tunable RF filter **602** is a first tunable RF receive filter **608**. Additionally, the RF front-end circuitry **58** further includes the RF receive circuitry **62** and RF detection circuitry **610**. The RF receive circuitry **62** illustrated in FIG. **38** may be similar to the RF receive circuitry **62** illustrated in FIG. **4**. The first tunable RF filter **602** is directly coupled to the first RF antenna **16** via the first common connection node **74**.

The first tunable RF receive filter **608** receives and filters the first upstream RF receive signal **RU1** via the first RF antenna **16** to provide the first filtered RF receive signal **RF1** to the RF receive circuitry **62** and to the RF detection circuitry **610** via the first connection node **70**. The RF receive circuitry **62** receives and processes the first filtered RF receive signal **RF1** to provide the first receive signal **RX1** to the RF system control circuitry **56**. Additionally, the RF detection circuitry **610** receives and detects the first filtered

57

RF receive signal RF1 to provide a first detected signal DS1 to the RF system control circuitry 56.

In one embodiment of the RF detection circuitry 610, detection of the first filtered RF receive signal RF1 is direct RF detection, which excludes any down-conversion of the first filtered RF receive signal RF1. By using direct RF detection, artifacts created by down-conversion techniques are avoided.

In a first embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is used to create a group of measurements using at least the first detected signal DS1 to obtain a profile of an RF communications band 612 (FIG. 40A) of interest. Therefore, the RF communications circuitry 54 operates as profiling circuitry to obtain the measurement-based RF spectrum profile 606. As such, the measurement-based RF spectrum profile 606 is based on the group of measurements, which are based on the RF communications band 612 (FIG. 40A). In one embodiment of the control circuitry 56, 98 (FIG. 39), the control circuitry 56, 98 (FIG. 39) constructs the measurement-based RF spectrum profile 606 based on the group of measurements. In one embodiment of the RF front-end circuitry 58, the RF receive circuitry 62 is omitted.

In a second embodiment of the RF communications circuitry 54, the measurement-based RF spectrum profile 606 was previously provided to the RF system control circuitry 56, and the RF communications circuitry 54 is used to receive RF signals for normal operations, such as normal RF communications. Therefore, the RF communications circuitry 54 operates as a slave, which uses a previously defined measurement-based RF spectrum profile 606. In one embodiment of the RF front-end circuitry 58, the RF detection circuitry 610 is omitted.

In a third embodiment of the RF communications circuitry 54, the RF communications circuitry 54 is used for both profiling and normal operations. As such, the control circuitry 56, 98 (FIG. 39) selects one of a normal operating mode and a profiling mode. During the profiling mode, the RF detection circuitry 610 provides at least the first detected signal DS1 for the group of measurements, which are used to construct the measurement-based RF spectrum profile 606. During the normal operating mode, the first tunable RF filter 602 receives and filters the upstream RF signal to provide the first filtered RF signal for normal operations. Therefore, the RF communications circuitry 54 operates autonomously. During the profiling mode, the RF communications circuitry 54 operates as profiling circuitry to obtain the measurement-based RF spectrum profile 606. During the normal operating mode, the RF communications circuitry 54 operates as a slave, which uses the measurement-based RF spectrum profile 606 that was obtained during the profiling mode.

In both embodiments of the first tunable RF filter 602 illustrated in FIGS. 37 and 38 in which the first tunable RF filter 602 is the first tunable RF transmit filter 604 and the first tunable RF receive filter 608, respectively, the center frequency, which is the tunable center frequency 626 (FIG. 40B) of the first tunable RF filter 602, is based on the first filter control signal FCS1. Further, in one embodiment of the first tunable RF filter 602, the first tunable RF filter 602 is the reconfigurable tunable RF filter 602, such that the shape of the transfer function of the first tunable RF filter 602 is reconfigurable. As such, in one embodiment of the first tunable RF filter 602, the configuration of the first tunable RF filter 602 is based on the first filter reconfiguration signal FCS1R.

58

FIG. 39 shows the RF communications circuitry 54 according to an additional embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 39 is similar to the RF communications circuitry 54 illustrated in FIG. 38, except in the RF communications circuitry 54 illustrated in FIG. 39, the RF front-end circuitry 58 further includes the RF front-end control circuitry 98 and the first detected signal DS1 includes a first detected amplitude modulation (AM) signal AM1 and a first detected phase modulation (PM) signal PM1. In an alternate embodiment of the first detected signal DS1, the first detected PM signal PM1 is omitted.

The RF system control circuitry 56 provides the front-end control signal FEC to the RF front-end control circuitry 98. The RF front-end control circuitry 98 provides the first filter control signal FCS1 and the first filter reconfiguration signal FCS1R to the first tunable RF filter 602 based on the front-end control signal FEC. The RF front-end control circuitry 98 provides the front-end status signal FES to the RF system control circuitry 56 based on the first detected signal DS1. As such, the control circuitry 56, 98 includes the RF system control circuitry 56, the RF front-end control circuitry 98, or both.

In one embodiment of the RF detection circuitry 610, the detection of the first filtered RF receive signal RF1 includes AM detection, such that the first detected AM signal AM1 is based on the AM detection. In one embodiment of the measurement-based RF spectrum profile 606, the measurement-based RF spectrum profile 606 is based on at least the first detected AM signal AM1.

In an alternate embodiment of the RF detection circuitry 610, the detection of the first filtered RF receive signal RF1 includes both AM detection and PM detection, such that the first detected AM signal AM1 is based on the AM detection and the first detected PM signal PM1 is based on the PM detection. In one embodiment of the measurement-based RF spectrum profile 606, the measurement-based RF spectrum profile 606 is based on at least the first detected AM signal AM1 and the first detected PM signal PM1.

FIG. 40A is a graph illustrating a profile of an RF communications band 612 of interest according to one embodiment of the RF communications band 612. The RF communications band 612 includes a group of active RF signals 614, such that each of the group of active RF signals 614 has a corresponding center frequency 616. FIG. 40B is a graph illustrating a first bandpass filter response 624 of the first tunable RF receive filter 608 (FIG. 39) according to one embodiment of the first tunable RF receive filter 608 (FIG. 39). The first tunable RF receive filter 608 (FIG. 39) has a tunable center frequency 626.

In one embodiment of the RF communications circuitry 54 (FIG. 39), the first tunable RF receive filter 608 (FIG. 39) is used to measure and profile the RF communications band 612 by identifying the active RF signals 614 in the RF communications band 612. The profile is used to develop the measurement-based RF spectrum profile 606 (FIG. 39) of the RF communications band 612. The active RF signals 614 may be blocking signals in some RF communications systems and desired signals in other RF communications systems. The measurement-based RF spectrum profile 606 (FIG. 39) may be used to help reject the blocking signals and accept the desired signals.

In this regard, in one embodiment of the control circuitry 56, 98 (FIG. 39), as previously mentioned, the control circuitry 56, 98 (FIG. 39) constructs the measurement-based RF spectrum profile 606 (FIG. 39) based on the group of measurements, which may be obtained by adjusting the

59

tunable center frequency **626** for each measurement until the entire RF communications band **612** has been profiled. As such, in one embodiment of the control circuitry **56**, **98** (FIG. **39**), at least a portion of the group of measurements is associated with at least a portion of the group of active RF signals **614**.

In one embodiment of the RF communications band **612**, the group of active RF signals **614** includes a pair of somewhat adjacent weak blockers **618**, a pair of adjacent strong blockers **620**, and a one-sided strong blocker **622**. Therefore, the tunable center frequency **626** of the first tunable RF receive filter **608** (FIG. **39**), the configuration of the first tunable RF receive filter **608** (FIG. **39**), or both may need to be adjusted based on a distribution of the active RF signals **614**.

FIG. **41A** is a graph illustrating the first bandpass filter response **624** and a second bandpass filter response **628** of the first tunable RF receive filter **608** shown in FIG. **38** according to one embodiment of the first tunable RF receive filter **608**. In general, in one embodiment of the first tunable RF filter **602** (FIG. **38**), the first tunable RF filter **602** (FIG. **38**) has either a first configuration or a second configuration based on the first filter reconfiguration signal FCS1R (FIG. **38**). During the first configuration, the first tunable RF filter **602** (FIG. **38**) has the first bandpass filter response **624**, and during the second configuration, the first tunable RF filter **602** (FIG. **38**) has the second bandpass filter response **628**. An order of the first tunable RF filter **602** (FIG. **38**) is higher during the second configuration than during the first configuration.

A bandwidth of the second bandpass filter response **628** is narrower than a bandwidth of the first bandpass filter response **624**, as shown in FIG. **41A**. As such, the first bandpass filter response **624** may have a lower slope away from the tunable center frequency **626** than the second bandpass filter response **628**. Additionally, in the second bandpass filter response **628**, insertion loss increases more rapidly as the frequency moves away from the tunable center frequency **626** than the second bandpass filter response **628**. However, the second bandpass filter response **628** has increased insertion loss **630** toward the tunable center frequency **626** when compared to the first bandpass filter response **624**. Therefore, the first configuration may be used when blockers are not close to the tunable center frequency **626**. However, the second configuration may be used when blockers are somewhat close to the tunable center frequency **626**, such as when the tunable center frequency **626** is between the somewhat adjacent weak blockers **618** (FIG. **40A**).

FIG. **41B** is a graph illustrating the first bandpass filter response **624** and a third bandpass filter response **632** of the first tunable RF receive filter **608** shown in FIG. **38** according to one embodiment of the first tunable RF receive filter **608**. The first bandpass filter response **624** is shown for comparison purposes. In general, in one embodiment of the first tunable RF filter **602** (FIG. **38**), the first tunable RF filter **602** (FIG. **38**) has the third bandpass filter response **632** based on the first filter reconfiguration signal FCS1R (FIG. **38**). The third bandpass filter response **632** includes a left-side notch filter response **634** and a right-side notch filter response **636**. As such, the left-side notch filter response **634** has a tunable left-side notch frequency **638** and the right-side notch filter response **636** has a tunable right-side notch frequency **640**.

A bandwidth of the third bandpass filter response **632** is narrower than the bandwidth of the first bandpass filter response **624**, as shown in FIG. **41B**. However, the third

60

bandpass filter response **632** has further increased insertion loss **642** toward the tunable center frequency **626** when compared to the first bandpass filter response **624**. In this regard, the third bandpass filter response **632** may be used when blockers are strong, close to the tunable center frequency **626**, or both, such as when the tunable center frequency **626** is between the adjacent strong blockers **620** (FIG. **40A**).

In an alternate embodiment of the first tunable RF filter **602** (FIG. **38**), the first tunable RF filter **602** (FIG. **38**) has the third bandpass filter response **632** based on the first filter reconfiguration signal FCS1R (FIG. **38**), except that either the left-side notch filter response **634** or the right-side notch filter response **636** is omitted. As such, the first tunable RF filter **602** (FIG. **38**) has a bandpass filter response with a side notch filter response. In this regard, the bandpass filter response with a side notch filter response may be used when a strong blocker on one side is close, such as when the tunable center frequency **626** is close to the one-sided strong blocker **622** (FIG. **40A**). Specifically, in one embodiment of the third bandpass filter response **632**, the right-side notch filter response **636** is omitted, such that the third bandpass filter response **632** has the left-side notch filter response **634** and not the right-side notch filter response **636**. Conversely, in an alternate embodiment of the third bandpass filter response **632**, the left-side notch filter response **634** is omitted, such that the third bandpass filter response **632** has the right-side notch filter response **636** and not the left-side notch filter response **634**.

FIG. **42** shows the RF communications circuitry **54** according to an alternate embodiment of the RF communications circuitry **54**. The RF communications circuitry **54** illustrated in FIG. **42** is similar to the RF communications circuitry **54** illustrated in FIG. **37**, except in the RF communications circuitry **54** illustrated in FIG. **42**, the antenna matching filter **600** is omitted, the RF front-end circuitry **58** further includes the RF receive circuitry **62**, and the first RF filter structure **60** further includes a second tunable RF filter **644**. The first tunable RF filter **602** is directly coupled to the first RF antenna **16** via the first common connection node **74**, and the second tunable RF filter **644** is directly coupled to the first RF antenna **16** via the first common connection node **74**. In one embodiment of the second tunable RF filter **644**, the second tunable RF filter **644** is the first tunable RF receive filter **608**.

The first tunable RF receive filter **608** receives and filters a first upstream RF receive signal via the first RF antenna **16** to provide the first filtered RF receive signal RF1 to the RF receive circuitry **62** via the second connection node **72**. The RF receive circuitry **62** receives and processes the first filtered RF receive signal RF1 to provide the first receive signal RX1 to the RF system control circuitry **56**.

The RF system control circuitry **56** provides a second filter control signal FCS2 and a second filter reconfiguration signal FCS2R to the second tunable RF filter **644** in general, and to the first tunable RF receive filter **608** in particular. In one embodiment of the second filter control signal FCS2, the second filter control signal FCS2 is based on the measurement-based RF spectrum profile **606**. In one embodiment of the second filter reconfiguration signal FCS2R, the second filter reconfiguration signal FCS2R is based on the measurement-based RF spectrum profile **606**. In an alternate embodiment of the RF communications circuitry **54**, the second filter reconfiguration signal FCS2R is omitted.

In general, in one embodiment of the second tunable RF filter **644**, the second tunable RF filter **644** receives and filters an upstream RF signal to provide a first filtered RF

61

signal, such that a center frequency, which is a tunable center frequency of the second tunable RF filter 644, is based on the second filter control signal FCS2. In one embodiment of the second tunable RF filter 644, the second tunable RF filter 644 is a reconfigurable tunable RF filter 644, such that a shape of a transfer function of the second tunable RF filter 644 is reconfigurable. As such, in one embodiment of the second tunable RF filter 644, a configuration of the second tunable RF filter 644 is based on the second filter reconfiguration signal FCS2R.

In one embodiment of the RF communications circuitry 54, the measurement-based RF spectrum profile 606 was previously provided to the RF system control circuitry 56, and the RF communications circuitry 54 is used to receive RF signals and transmit RF signals for normal operations, such as normal RF communications using the measurement-based RF spectrum profile 606.

FIG. 43 shows the RF communications circuitry 54 according to an alternate embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 43 is similar to the RF communications circuitry 54 illustrated in FIG. 42, except in the RF communications circuitry 54 illustrated in FIG. 43, the RF front-end circuitry 58 further includes the second RF filter structure 120, such that the second tunable RF filter 644 is omitted from the first RF filter structure 60 and then added to the second RF filter structure 120.

FIG. 44 shows the RF communications circuitry 54 according to an additional embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 44 is similar to the RF communications circuitry 54 illustrated in FIG. 38, except in the RF communications circuitry 54 illustrated in FIG. 44, the RF receive circuitry 62 is omitted and the first RF filter structure 60 further includes the second tunable RF filter 644 and up to and including an  $N^{TH}$  tunable RF filter 646. Also, the first RF filter structure 60 further includes up to and including an  $N^{TH}$  connection node 648. In one embodiment of the second tunable RF filter 644 and the second tunable RF receive filter 650, the second tunable RF filter 644 is a second tunable RF receive filter 650 and the  $N^{TH}$  tunable RF filter 646 is an  $N^{TH}$  tunable RF receive filter 652.

The RF detection circuitry 610 provides the first detected signal DS1, a second detected signal DS2, and an  $N^{TH}$  detected signal DSN to the RF system control circuitry 56 based on receiving and detecting the first filtered RF receive signal RF1, the second filtered RF receive signal RF2 and up to and including an  $N^{TH}$  filtered RF receive signal RFN. The RF system control circuitry 56 provides the first filter control signal FCS1, the second filter control signal FCS2, and up to and including an  $N^{TH}$  filter control signal FCSN to the RF detection circuitry 610. Additionally, the RF system control circuitry 56 provides the first filter reconfiguration signal FCS1R, the second filter reconfiguration signal FCS2R, and up to and including an  $N^{TH}$  filter reconfiguration signal FCSNR to the RF front-end circuitry 58.

In general, the first RF filter structure 60 includes a group of tunable RF filters 602, 644, 646 and a group of connection nodes 70, 72, 648. The RF system control circuitry 56 provides a group of filter control signals FCS1, FCS2, FCSN to the group of tunable RF filters 602, 644, 646 to tune the group of tunable RF filters 602, 644, 646. Additionally, the RF system control circuitry 56 provides a group of filter reconfiguration signals FCS1R, FCS2R, FCSNR to configure the group of tunable RF filters 602, 644, 646. The group of tunable RF filters 602, 644, 646 provides a group of filtered RF signals RF1, RF2, RFN to the RF detection

62

circuitry 610 via the group of connection nodes 70, 72, 648. The RF detection circuitry 610 receives and detects the group of filtered RF signals RF1, RF2, RFN to provide a group of detected signals DS1, DS2, DSN. The measurement-based RF spectrum profile 606 is based on a group of measurements using the group of detected signals DS1, DS2, DSN. In one embodiment of the RF detection circuitry 610, the RF detection circuitry 610 includes multiple AM detectors (not shown) and multiple PM detectors (not shown), such that each of the group of detected signals DS1, DS2, DSN has a corresponding detected AM signal and a corresponding detected PM signal.

FIG. 45 shows the RF communications circuitry 54 according to another embodiment of the RF communications circuitry 54. The RF communications circuitry 54 illustrated in FIG. 45 is similar to the RF communications circuitry 54 illustrated in FIG. 43, except in the RF communications circuitry 54 illustrated in FIG. 45, the RF front-end circuitry 58 further includes the RF front-end control circuitry 98.

The RF front-end control circuitry 98 provides the first calibration control signal CCS1 and up to and including the  $N^{TH}$  calibration control signal CCSN to the first RF filter structure 60. The RF front-end control circuitry 98 provides the  $P^{TH}$  calibration control signal CCSP and up to and including the  $X^{TH}$  calibration control signal CCSX to the second RF filter structure 120. Details of the first RF filter structure 60 and the second RF filter structure 120 are not shown to simplify FIG. 45.

The first RF filter structure 60 provides the first calibration status signal CSS1 and up to and including the  $Q^{TH}$  calibration status signal CSSQ to the RF front-end control circuitry 98. The second RF filter structure 120 provides the  $R^{TH}$  calibration status signal CSSR and up to and including the  $Y^{TH}$  calibration status signal CSSY to the RF front-end control circuitry 98. In an alternate embodiment of the RF front-end circuitry 58, any or all of the  $N^{TH}$  calibration control signal CCSN, the  $Q^{TH}$  calibration status signal CSSQ, the  $X^{TH}$  calibration control signal CCSX, and the  $Y^{TH}$  calibration status signal CSSY are omitted.

In one embodiment of the RF front-end circuitry 58, the RF front-end circuitry 58 operates in one of a normal operating mode and a calibration mode. During the calibration mode, the RF front-end control circuitry 98 performs a calibration of the first RF filter structure 60, the second RF filter structure 120, or both. As such, the RF front-end control circuitry 98 provides any or all of the filter control signals FCS1, FCS2, any or all of the filter reconfiguration signals FCS1R, FCS2R, and any or all of the calibration control signals CCS1, CCSN, CCSP, CCSX needed for calibration. Further, the RF front-end control circuitry 98 receives any or all of the calibration status signals CSS1, CSSQ, CSSR, CSSY needed for calibration.

During the normal operating mode, the RF front-end control circuitry 98 provides any or all of the filter control signals FCS1, FCS2, any or all of the filter reconfiguration signals FCS1R, FCS2R, and any or all of the calibration control signals CCS1, CCSN, CCSP, CCSX needed for normal operation. Further, the RF front-end control circuitry 98 receives any or all of the calibration status signals CSS1, CSSQ, CSSR, CSSY needed for normal operation. Any or all of the calibration control signals CCS1, CCSN, CCSP, CCSX may be based on the front-end control signal FEC. The front-end status signal FES may be based on any or all of the calibration status signals CSS1, CSSQ, CSSR, CSSY. Further, during the normal operating mode, the RF front-end circuitry 58 processes signals as needed for normal opera-

63

tion. Other embodiments described in the present disclosure may be associated with normal operation.

FIG. 46 shows the first RF filter structure 60 shown in FIG. 45 according to one embodiment of the first RF filter structure 60. The first RF filter structure 60 includes the first tunable RF filter 602 and RF filter tuning, configuration, and calibration circuitry 654. The RF filter tuning, configuration, and calibration circuitry 654 is used to facilitate tuning, configuration, and calibration of the first tunable RF filter 602. As such, the RF filter tuning, configuration, and calibration circuitry 654 receives the first filter control signal FCS1 and the first filter reconfiguration signal FCS1R. The RF filter tuning, configuration, and calibration circuitry 654 further receives the first calibration control signal CCS1 and up to and including the  $N^{TH}$  calibration control signal CCSN. The RF filter tuning, configuration, and calibration circuitry 654 provides the first calibration status signal CSS1 and up to and including the  $Q^{TH}$  calibration status signal CSSQ.

The first tunable RF filter 602 includes a first resonator 656, a second resonator 658, a third resonator 660, a fourth resonator 662, a first coupling circuit 664, a second coupling circuit 666, a third coupling circuit 668, a fourth coupling circuit 670, and a fifth coupling circuit 672. The first resonator 656 is coupled to the first connection node 70 and the second resonator 658 is coupled to the first common connection node 74. In general, the first filter control signal FCS1 is used to tune center frequencies of the resonators 656, 658, 660, 662 and the first filter reconfiguration signal FCS1R is used to configure the coupling circuits 664, 666, 668, 670, 672 to provide connectivity between the resonators 656, 658, 660, 662.

In one embodiment of the coupling circuits 664, 666, 668, 670, 672, each of the coupling circuits 664, 666, 668, 670, 672 may be configured to provide no connectivity or a configurable magnitude of connectivity between two of the resonators 656, 658, 660, 662. Further, in one embodiment of the coupling circuits 664, 666, 668, 670, 672, each of the coupling circuits 664, 666, 668, 670, 672 may be configured to provide either additive or subtractive connectivity between two of the resonators 656, 658, 660, 662. In the embodiments that follow, unless stated otherwise, each of the coupling circuits 664, 666, 668, 670, 672 provides no connectivity between the resonators 656, 658, 660, 662.

In a first embodiment of the first tunable RF filter 602, the first tunable RF filter 602 has a first configuration based on the first filter reconfiguration signal FCS1R, as illustrated in FIG. 46. In the first configuration, the first coupling circuit 664 is configured to couple the first resonator 656 to the second resonator 658, thereby providing a first reconfigurable RF filter path 674 between the first connection node 70 and the first common connection node 74 via the first resonator 656, the first coupling circuit 664, and the second resonator 658. A first group of resonators includes the first resonator 656 and the second resonator 658. Therefore, the first group of resonators includes two resonators. In this regard, during the first configuration, the first group of resonators are coupled in series between the first connection node 70 and the first common connection node 74.

FIG. 47 shows the first RF filter structure 60 shown in FIG. 45 according to an alternate embodiment of the first RF filter structure 60. The first RF filter structure 60 illustrated in FIG. 47 is similar to the first RF filter structure 60 illustrated in FIG. 46, except in the first RF filter structure 60 illustrated in FIG. 47, the first tunable RF filter 602 has a second configuration instead of the first configuration.

64

As such, in a second embodiment of the first tunable RF filter 602, the first tunable RF filter 602 has the second configuration based on the first filter reconfiguration signal FCS1R, as illustrated in FIG. 47. In the second configuration, the first coupling circuit 664 provides no connectivity, the second coupling circuit 666 is configured to couple the first resonator 656 to the third resonator 660, and the third coupling circuit 668 is configured to couple the third resonator 660 to the second resonator 658, thereby providing a second reconfigurable RF filter path 676 between the first connection node 70 and the first common connection node 74 via the first resonator 656, the second coupling circuit 666, the third resonator 660, the third coupling circuit 668, and the second resonator 658. A second group of resonators includes the first resonator 656, the second resonator 658, and the third resonator 660. Therefore, the second group of resonators includes three resonators. A first group of coupling circuits includes the second coupling circuit 666 and the third coupling circuit 668. In this regard, during the second configuration, the second group of resonators and the first group of coupling circuits are coupled in series between the first connection node 70 and the first common connection node 74.

The first tunable RF filter 602 illustrated in FIGS. 46 and 47 has a bandpass filter response. However, since the second group of resonators has more resonators than the first group of resonators, an order of the first tunable RF filter 602 is higher during the second configuration than during the first configuration. Further, during both the first configuration and the second configuration, the first tunable RF filter 602 has a single path between the first connection node 70 and the first common connection node 74.

FIG. 48 shows the first RF filter structure 60 shown in FIG. 45 according to an additional embodiment of the first RF filter structure 60. The first tunable RF filter 602 illustrated in FIG. 48 combines the first configuration and the second configuration illustrated in FIGS. 46 and 47, respectively. As such, the first tunable RF filter 602 illustrated in FIG. 48 includes the first reconfigurable RF filter path 674 and the second reconfigurable RF filter path 676. As such, the first reconfigurable RF filter path 674 and the second reconfigurable RF filter path 676 share at least one resonator. Further, the first tunable RF filter 602 includes the first group of resonators and the second group of resonators, such that the first group of resonators is not identical to the second group of resonators. By combining the first reconfigurable RF filter path 674 and the second reconfigurable RF filter path 676, the first tunable RF filter 602 illustrated in FIG. 48 has a bandpass filter response with a side notch filter response.

FIG. 49 shows the first RF filter structure 60 shown in FIG. 45 according to another embodiment of the first RF filter structure 60. The first tunable RF filter 602 illustrated in FIG. 49 combines the first reconfigurable RF filter path 674 and the second reconfigurable RF filter path 676 illustrated in FIG. 48 with a third reconfigurable RF filter path 678. As such, in a third embodiment of the first tunable RF filter 602, the first tunable RF filter 602 has a third configuration based on the first filter reconfiguration signal FCS1R, as illustrated in FIG. 49. In the third configuration, the first reconfigurable RF filter path 674, the second reconfigurable RF filter path 676, and the third reconfigurable RF filter path 678 are provided.

In the third reconfigurable RF filter path 678, the fourth coupling circuit 670 is configured to couple the first resonator 656 to the fourth resonator 662, and the fifth coupling circuit 672 is configured to couple the fourth resonator 662

65

to the second resonator **658**, thereby providing the third reconfigurable RF filter path **678** between the first connection node **70** and the first common connection node **74** via the first resonator **656**, the fourth coupling circuit **670**, the fourth resonator **662**, the fifth coupling circuit **672**, and the second resonator **658**. A third group of resonators includes the first resonator **656**, the second resonator **658**, and the fourth resonator **662**.

As such, the first reconfigurable RF filter path **674**, the second reconfigurable RF filter path **676**, and the third reconfigurable RF filter path **678** share at least one resonator. Further, the first tunable RF filter **602** includes the first group of resonators, the second group of resonators, and the third group of resonators, such that the first group of resonators is not identical to the second group of resonators, the second group of resonators is not identical to the third group of resonators, and the first group of resonators is not identical to the third group of resonators. By combining the first reconfigurable RF filter path **674**, the second reconfigurable RF filter path **676**, and the third reconfigurable RF filter path **678**, the first tunable RF filter **602** illustrated in FIG. **49** has a bandpass filter response with a left-side notch filter response and a right-side notch filter response.

FIG. **50** shows one embodiment of the RF communications circuitry **54** and alternate RF communications circuitry **680**. The RF communications circuitry **54** includes the control circuitry **56**, **98** (FIG. **39**), which includes the measurement-based RF spectrum profile **606**. The measurement-based RF spectrum profile **606** may be useful for configuration of other RF communications systems. As such, the RF communications circuitry **54** provides the measurement-based RF spectrum profile **606** to the alternate RF communications circuitry **680** via an information transfer system **682**. The information transfer system **682** may be manual or automated and may include any combination of analog circuitry, digital circuitry, wireless circuitry, communications circuitry, data storage circuitry, the like, or any combination thereof.

FIG. **51** shows an electronics apparatus **700** according to one embodiment of the electronics apparatus **700**. Many electronics systems may have complex nonlinear capacitance effects. Such effects may be non-correlated or weakly correlated, thereby degrading performance of such electronics systems. Embodiments of the present disclosure present techniques for mitigating such effects.

The electronics apparatus **700** includes a first electronic device **702**; nonlinear capacitance compensation circuitry **704**, which includes a first nonlinear capacitance compensation circuit **706** and a capacitance compensation control circuit **708**; a first sensor **710**, and a first replica circuit **712**. In an alternate embodiment of the electronics apparatus **700**, either or both of the first sensor **710** and the first replica circuit **712** may be omitted.

The first electronic device **702** has a first nonlinear capacitance CN, which has at least one nonlinearity that may adversely affect behavior of the first electronic device **702**. The first nonlinear capacitance compensation circuit **706** has a first compensation capacitance CC. The first electronic device **702** is coupled to the first nonlinear capacitance compensation circuit **706**. In one embodiment of the first electronic device **702** and the first nonlinear capacitance compensation circuit **706**, the first electronic device **702** is coupled to the first nonlinear capacitance compensation circuit **706** using differential coupling as shown. In an alternate embodiment of the first electronic device **702** and the first nonlinear capacitance compensation circuit **706**, the first electronic device **702** is coupled to the first nonlinear

66

capacitance compensation circuit **706** using a single-ended coupling as shown in FIG. **52**. The first compensation capacitance CC is used to at least partially linearize the first nonlinear capacitance CN.

The capacitance compensation control circuit **708** receives a first status signal SS1, which is representative of a cause of nonlinearity of the first nonlinear capacitance CN. The first status signal SS1 may be provided by internal circuitry in the first electronic device **702**, by signals that are external to the first electronic device **702**, or by the coupling between the first electronic device **702** and the first nonlinear capacitance compensation circuit **706**. As such, the first status signal SS1 may be a differential signal, a single-ended signal, or any type of signal that is representative of a cause of nonlinearity of the first nonlinear capacitance CN.

The capacitance compensation control circuit **708** provides a first compensation control signal SC1 to the first nonlinear capacitance compensation circuit **706**. As such, in one embodiment of the electronics apparatus **700**, the first electronic device **702** has the first nonlinear capacitance CN and is coupled to the first nonlinear capacitance compensation circuit **706**. The first nonlinear capacitance compensation circuit **706** has the first compensation capacitance CC and receives the first compensation control signal SC1. The capacitance compensation control circuit **708** adjusts the first compensation capacitance CC using the first compensation control signal SC1 to at least partially linearize the first nonlinear capacitance CN. In one embodiment of the capacitance compensation control circuit **708**, the capacitance compensation control circuit **708** adjusts the first compensation capacitance CC using the first compensation control signal SC1 to substantially linearize the first nonlinear capacitance CN.

The first sensor **710** provides a first sensor signal SN1 to the capacitance compensation control circuit **708**. The first replica circuit **712** provides a first replica signal SR1 to the capacitance compensation control circuit **708**. The capacitance compensation control circuit **708** receives system information SIN from one or more other sources (not shown). In this regard, any or all of the first sensor signal SN1, the first replica signal SR1, and the system information SIN may provide at least a first system factor to the capacitance compensation control circuit **708**.

In this regard, in one embodiment of the electronics apparatus **700** at least the first system factor, the first status signal SS1, or both are representative of a cause of nonlinearity of the first nonlinear capacitance CN. Therefore, in general, the capacitance compensation control circuit **708** adjusts the first compensation capacitance CC using the first compensation control signal SC1 to at least partially linearize the first nonlinear capacitance CN based on at least the first system factor, the first status signal SS1, or both.

In one embodiment of the electronics apparatus **700**, the first sensor **710** is used to sense at least one parameter in the electronics apparatus **700** that is representative of one or more system factors, which may include the first system factor. As such, in one embodiment of the first sensor **710**, the first system factor is based on the first sensor **710**. The first replica circuit **712** is used to replicate at least one circuit in the electronics apparatus **700** that is representative of one or more system factors, which may include the first system factor. In one embodiment of the first replica circuit **712**, the first system factor is based on the first replica circuit **712**.

In one embodiment of at least the first system factor, at least the first system factor includes temperature of the electronics apparatus **700**, manufacturing process related variations of the electronics apparatus **700**, one or more

67

nonlinear parasitic element of the electronics apparatus 700, one or more nonlinear substrate element of the electronics apparatus 700, one or more power supply voltage of the electronics apparatus 700, one or more power supply current of the electronics apparatus 700, one or more signal amplitude of the electronics apparatus 700, one or more signal frequency of the electronics apparatus 700, operating frequency band of the electronics apparatus 700, operating communications standard, modulation technique of the electronics apparatus 700, the like, or any combination thereof.

In alternate embodiments of the electronics apparatus 700, either the first sensor 710, the first replica circuit 712, or both are omitted. In alternate embodiments of the electronics apparatus 700, any or all of the first status signal SS1, the first replica signal SR1, the system information SIN, and the first sensor signal SN1 are omitted.

FIG. 52 shows the electronics apparatus 700 according to an alternate embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 52 is similar to the electronics apparatus 700 illustrated in FIG. 51, except in the electronics apparatus 700 illustrated in FIG. 52, the first electronic device 702 is coupled to the first nonlinear capacitance compensation circuit 706 using a single-ended coupling instead of a differential coupling, and the first status signal SS1 is taken from the coupling between the first electronic device 702 to the first nonlinear capacitance compensation circuit 706 that is inside the nonlinear capacitance compensation circuitry 704. Additionally, the first electronic device 702 receives an input signal VIN.

FIGS. 53A, 53B, and 53C are graphs illustrated relationships between the input signal VIN and a linear capacitance CL, the input signal VIN and the first nonlinear capacitance CN, and the input signal VIN and the first compensation capacitance CC, respectively. From FIG. 53A, as the input signal VIN varies above and below a bias point 714, the linear capacitance CL varies in a linear manner. Even though the linear capacitance CL is not constant as the input signal VIN varies, since the capacitance variation is linear, many circuits will have well-behaved performance. For example, effects caused by voltages above the bias point 714 will largely be cancelled by effects caused below the bias point 714.

However, in FIG. 53B, as the input signal VIN varies above and below the bias point 714, the first nonlinear capacitance CN varies in a nonlinear manner. As such, effects caused by voltages above the bias point 714 will not be cancelled by effects caused below the bias point 714. As such, this nonlinearity may cause problems in certain circuits.

In FIG. 53C, as the input signal VIN varies above and below the bias point 714, the first compensation capacitance CC also varies in a nonlinear manner. However, the first nonlinear capacitance CN in FIG. 53B curves upward at high magnitudes of the input signal VIN, whereas the first compensation capacitance CC in FIG. 53C curves downward at high magnitudes of the input signal VIN.

Therefore, by using the first compensation capacitance CC to at least partially linearize the first nonlinear capacitance CN, a combination of the first nonlinear capacitance CN and the first compensation capacitance CC produces a net response that is closer to the response of the linear capacitance CL.

The response of the first nonlinear capacitance CN is only nonlinear in the area at the right of FIG. 53B. In general, the first nonlinear capacitance CN may be linear in some areas and nonlinear in others. Therefore, in one embodiment of the capacitance compensation control circuit 708 (FIG. 1), the

68

capacitance compensation control circuit 708 (FIG. 1) adjusts the first compensation capacitance CC based on a piece-wise function.

FIG. 54 shows the electronics apparatus 700 according to one embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 54 includes the nonlinear capacitance compensation circuitry 704 and the first electronic device 702, which is an RF amplifier 716. The RF amplifier 716 receives and amplifies an input signal VIN to provide an output signal VOUT. The nonlinear capacitance compensation circuitry 704 is coupled to an output from the RF amplifier 716. The RF amplifier 716 has an amplifier output capacitance CNA, which is presented to the output from the RF amplifier 716. As such, the first nonlinear capacitance CN is the amplifier output capacitance CNA.

In one embodiment of the RF amplifier 716, the RF amplifier 716 is a power amplifier. In one embodiment of the RF amplifier 716, the RF amplifier 716 is a low noise amplifier. In one embodiment of the RF amplifier 716, the RF amplifier 716 is a complementary metal-oxide-semiconductor (CMOS) amplifier. In one embodiment of the RF amplifier 716, the RF amplifier 716 is a silicon-on-insulator (SOI) amplifier.

FIG. 55A shows the electronics apparatus 700 according to an alternate embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 55A includes the nonlinear capacitance compensation circuitry 704 and the first electronic device 702, which is an RF filter 718. The RF filter 718 receives and filters an input signal VIN to provide an output signal VOUT. The nonlinear capacitance compensation circuitry 704 is coupled to the RF filter 718. The RF filter 718 has an RF filter capacitance CNF. As such, the first nonlinear capacitance CN is the RF filter capacitance CNF.

FIG. 55B shows the electronics apparatus 700 according to an additional embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 55B includes the nonlinear capacitance compensation circuitry 704 and the first electronic device 702, which is an RF oscillator 720. The RF oscillator 720 provides an output signal VOUT. The nonlinear capacitance compensation circuitry 704 is coupled to the RF oscillator 720. The RF oscillator 720 has an RF oscillator capacitance CNO. As such, the first nonlinear capacitance CN is the RF oscillator capacitance CNO.

In one embodiment of the electronics apparatus 700, the capacitance compensation control circuit 708 adjusts the first compensation capacitance CC (FIG. 2) to reduce frequency error in the RF oscillator 720 using the first compensation control signal SC1 (FIG. 2). In one embodiment of the electronics apparatus 700, the capacitance compensation control circuit 708 adjusts the first compensation capacitance CC (FIG. 2) to reduce phase noise in the RF oscillator 720 using the first compensation control signal SC1 (FIG. 2).

FIG. 56 shows the electronics apparatus 700 according to one embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 56 includes the nonlinear capacitance compensation circuitry 704 and the first electronic device 702, which is a first RF switch 722. The nonlinear capacitance compensation circuitry 704 is coupled across the first RF switch 722. When the first RF switch 722 is in an OFF state, as shown in FIG. 56, the first RF switch 722 has an OFF state capacitance CFS, which is presented across the first RF switch 722. As such, the first nonlinear capacitance CN is the OFF state capacitance CFS.

69

FIG. 57 shows the electronics apparatus 700 according to an alternate embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 57 includes the nonlinear capacitance compensation circuitry 704 and the first electronic device 702, which is the first RF switch 722. The nonlinear capacitance compensation circuitry 704 is coupled across the first RF switch 722. When the first RF switch 722 is in an ON state, as shown in FIG. 57, the first RF switch 722 has an ON state capacitance COS, which is presented across the first RF switch 722. As such, the first nonlinear capacitance CN is ON state capacitance COS.

FIG. 58 shows the electronics apparatus 700 according to an additional embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 58 is similar to the electronics apparatus 700 illustrated in FIG. 56, except in the electronics apparatus 700 illustrated in FIG. 58, the electronics apparatus 700 further includes a first capacitive element 724 coupled to the first RF switch 722.

FIG. 59 shows the electronics apparatus 700 according to one embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 59 is similar to the electronics apparatus 700 illustrated in FIG. 56, except in the electronics apparatus 700 illustrated in FIG. 59, the first RF switch 722 is a MOS transistor element 726. The MOS transistor element 726 has a drain 728, a source 730, and a body 732. The MOS transistor element 726 has a drain-to-source capacitance CDS between the drain 728 and the source 730. As such, the first nonlinear capacitance CN is the drain-to-source capacitance CDS. Therefore, the nonlinear capacitance compensation circuitry 704 is coupled between the drain 728 and the source 730.

FIG. 60 shows the electronics apparatus 700 according to an alternate embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 60 is similar to the electronics apparatus 700 illustrated in FIG. 51, except in the electronics apparatus 700 illustrated in FIG. 60, the first sensor 710, the first replica circuit 712, the system information SIN, and the first status signal SS1 are not shown to simplify FIG. 60. Embodiments of the electronics apparatus 700 illustrated in FIG. 60 may include any or all of the first sensor 710, the first replica circuit 712, the system information SIN, and the first status signal SS1 even though they are not shown.

The first electronic device 702 further has a second nonlinear capacitance CN2. The first nonlinear capacitance compensation circuit 706 further has a second compensation capacitance CC2. The first electronic device 702 is further coupled to the first nonlinear capacitance compensation circuit 706 as shown. The capacitance compensation control circuit 708 further provides a second compensation control signal SC2 to the first nonlinear capacitance compensation circuit 706. As such, the capacitance compensation control circuit 708 adjusts the second compensation capacitance CC2 using the second compensation control signal SC2 to at least partially linearize the second nonlinear capacitance CN2. In one embodiment of the capacitance compensation control circuit 708, the capacitance compensation control circuit 708 adjusts the second compensation capacitance CC2 using the second compensation control signal SC2 to substantially linearize the second nonlinear capacitance CN2.

FIG. 61 shows the electronics apparatus 700 according to an additional embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 61 is similar to the electronics apparatus 700 illustrated in FIG. 59, except in the electronics apparatus 700 illustrated in FIG. 61, the nonlinear capacitance compensation circuitry 704 is

70

similar to the nonlinear capacitance compensation circuitry 704 illustrated in FIG. 60. In this regard, the MOS transistor element 726 has a drain-to-body capacitance CDB between the drain 728 and the body 732. The MOS transistor element 726 further has a source-to-body capacitance CSB between the source 730 and the body 732. As such, the first nonlinear capacitance CN is the drain-to-body capacitance CDB and the second nonlinear capacitance CN2 is the source-to-body capacitance CSB.

FIG. 62 shows the electronics apparatus 700 according to another embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 62 is similar to the electronics apparatus 700 illustrated in FIG. 60, except in the electronics apparatus 700 illustrated in FIG. 62, the capacitance compensation control circuit 708 is replaced with a bias circuit 734. As such, the bias circuit 734 provides a first bias signal SB1 and a second bias signal SB2 to the first nonlinear capacitance compensation circuit 706 to replace the first compensation control signal SC1 and the second compensation control signal SC2, respectively.

In this regard, the first nonlinear capacitance compensation circuit 706 adjusts the first compensation capacitance CC and the second compensation capacitance CC2 based on the the first bias signal SB1 and the second bias signal SB2, respectively, to at least partially linearize the first nonlinear capacitance CN and the second nonlinear capacitance CN2, respectively. Additionally, the bias circuit 734 provides the first bias signal SB1 and the second bias signal SB2 to the first electronic device 702 to provide biasing of the first electronic device 702. In an additional embodiment of the electronics apparatus 700, the second bias signal SB2, the second nonlinear capacitance CN2, and the second compensation capacitance CC2 are omitted.

FIG. 63 shows the electronics apparatus 700 according to a further embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 63 is similar to the electronics apparatus 700 illustrated in FIG. 61, except in the electronics apparatus 700 illustrated in FIG. 63, the capacitance compensation control circuit 708 is replaced with the bias circuit 734. As such, the bias circuit 734 provides a bias between the drain 728 and the body 732 of the MOS transistor element 726 via the first bias signal SB1 (FIG. 62) and further provides a bias between the source 730 and the body 732 via the second bias signal SB2 (FIG. 62).

FIG. 64 shows the first nonlinear capacitance compensation circuit 706 illustrated in FIG. 52 according to one embodiment of the first nonlinear capacitance compensation circuit 706. The first nonlinear capacitance compensation circuit 706 includes a varactor diode 736, a varactor bias circuit 738, and a bias isolation capacitive element 740. The varactor diode 736 has the first compensation capacitance CC. The varactor diode 736 is coupled to the first electronic device 702 (FIG. 52) via the bias isolation capacitive element 740. The varactor bias circuit 738 provides a varactor diode bias signal to the varactor diode 736 to adjust the first compensation capacitance CC. The bias isolation capacitive element 740 substantially isolates the varactor diode bias signal from the first electronic device 702 (FIG. 52). In one embodiment of the varactor diode 736, the varactor diode 736 is a MOS varactor. In an alternate embodiment of the varactor diode 736, the varactor diode 736 is a junction diode varactor.

FIG. 65 shows the electronics apparatus 700 according to one embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 65 is similar to the electronics apparatus 700 illustrated in FIG. 51, except in the electronics apparatus 700 illustrated in FIG. 65 the

71

first electronic device 702 (FIG. 1) is not shown and the electronics apparatus 700 further includes a group 742 of electronic devices, a first connection node 744, and a second connection node 746.

The group 742 of electronic devices is coupled in series between the first connection node 744 and the second connection node 746. The group 742 of electronic devices includes the first electronic device 702 (FIG. 1). The first nonlinear capacitance compensation circuit 706 is coupled between the first connection node 744 and the second connection node 746. Each of the group 742 of electronic devices has a corresponding one of a group of nonlinear capacitances. The capacitance compensation control circuit 708 adjusts the first compensation capacitance CC (FIG. 1) to at least partially linearize at least one of the group of nonlinear capacitances.

FIG. 66 shows the electronics apparatus 700 according to an alternate embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 66 is similar to the electronics apparatus 700 illustrated in FIG. 65, except in the electronics apparatus 700 illustrated in FIG. 66, the first nonlinear capacitance compensation circuit 706 is replaced with a group 748 of nonlinear capacitance compensation circuits, which are coupled in series between the first connection node 744 and the second connection node 746. As such, each of the group 748 of nonlinear capacitance compensation circuits is coupled to a corresponding one of the group 742 of electronic devices.

The group 742 of electronic devices includes the first electronic device 702 (FIG. 1). Each of the group 742 of electronic devices has a corresponding one of a group of nonlinear capacitances. The group 748 of nonlinear capacitance compensation circuits includes the first nonlinear capacitance compensation circuit 706. Each of the group 748 of nonlinear capacitance compensation circuits has a corresponding one of a group of compensation capacitances. The capacitance compensation control circuit 708 adjusts at least two of the group of compensation capacitances to at least partially linearize at least two of the group of nonlinear capacitances.

FIG. 67 shows the electronics apparatus 700 according to an additional embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 67 is similar to the electronics apparatus 700 illustrated in FIG. 66, except in the electronics apparatus 700 illustrated in FIG. 67, the nonlinear capacitance compensation circuitry 704 further includes a fine nonlinear capacitance compensation circuit 750 coupled between the first connection node 744 and the second connection node 746. The capacitance compensation control circuit 708 (FIG. 66) is not shown to simplify FIG. 67.

In this regard, the group of compensation capacitances are coarse compensation capacitances. The fine nonlinear capacitance compensation circuit 750 has a fine compensation capacitance. The capacitance compensation control circuit 708 (FIG. 66) adjusts the fine compensation capacitance to further partially linearize at least a portion of the group of nonlinear capacitances.

FIG. 68 shows the electronics apparatus 700 according to another embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 68 is similar to the electronics apparatus 700 illustrated in FIG. 67, except in the electronics apparatus 700 illustrated in FIG. 68, the group 742 of electronic devices includes a group 752 of sub-switches coupled between the first connection node 744 and the second connection node 746.

72

FIG. 69 shows the electronics apparatus 700 according to a further embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 69 is similar to the electronics apparatus 700 illustrated in FIG. 67, except in the electronics apparatus 700 illustrated in FIG. 69, the group 742 of electronic devices includes a group 754 of amplifier stages coupled between the first connection node 744 and the second connection node 746.

FIG. 70 shows the electronics apparatus 700 according to one embodiment of the electronics apparatus 700. The electronics apparatus 700 illustrated in FIG. 70 is similar to the electronics apparatus 700 illustrated in FIG. 63, except the electronics apparatus 700 illustrated in FIG. 70 further includes a transistor bias circuit 756, which biases the MOS transistor element 726 shown in FIG. 70 instead of the MOS transistor element 726 being biased by the bias circuit 734.

FIGS. 71A, 71B, 71C, and 71D are graphs illustrating linearity responses of the first nonlinear capacitance CN, the first compensation capacitance CC, a first elementary response E1 of the first nonlinear capacitance compensation circuit 706, and a second elementary response E2 of the first nonlinear capacitance compensation circuit 706, respectively, shown in FIG. 51.

The linearity response of the first compensation capacitance CC is the response required to at least partially linearize the response of the first nonlinear capacitance CN. However, the response of the first compensation capacitance CC may be too complex to be provided by a single corrective element. Therefore, in one embodiment of the first nonlinear capacitance compensation circuit 706, two or more elementary responses may need to be combined to provide the required response for the first compensation capacitance CC. In this regard, the first elementary response E1 and the second elementary response E2 may be combined to provide the response of the first compensation capacitance CC. As such, the capacitance compensation control circuit 708 (FIG. 1) adjusts the first compensation capacitance CC based on a piece-wise function.

Those skilled in the art will recognize improvements and modifications to the preferred embodiments of the present disclosure. All such improvements and modifications are considered within the scope of the concepts disclosed herein and the claims that follow.

What is claimed is:

1. An apparatus comprising:

- a first electronic device having a first nonlinear capacitance and coupled to a first nonlinear capacitance compensation circuit;
- a first replica circuit;
- the first nonlinear capacitance compensation circuit having a first compensation capacitance and configured to receive a first compensation control signal; and
- a capacitance compensation control circuit configured to adjust the first compensation capacitance based on the first replica circuit using the first compensation control signal to at least partially linearize the first nonlinear capacitance.

2. The apparatus of claim 1 wherein the first electronic device is an RF amplifier and the first nonlinear capacitance is an amplifier output capacitance of the RF amplifier.

3. The apparatus of claim 2 wherein the RF amplifier is a power amplifier.

4. The apparatus of claim 2 wherein the RF amplifier is a low noise amplifier.

5. The apparatus of claim 2 wherein the RF amplifier is a complementary metal-oxide-semiconductor (CMOS) amplifier.

73

6. The apparatus of claim 2 wherein the RF amplifier is a silicon-on-insulator (SOI) amplifier.

7. The apparatus of claim 1 wherein the first electronic device further has a second nonlinear capacitance, the first nonlinear capacitance compensation circuit further has a second compensation capacitance and is further configured to receive a second compensation control signal, and the capacitance compensation control circuit is further configured to adjust the second compensation capacitance using the second compensation control signal to at least partially linearize the second nonlinear capacitance.

8. The apparatus of claim 7 wherein the first electronic device is a first RF switch, which is a MOS transistor element comprising a drain, a source, and a body, such that the first nonlinear capacitance is a drain-to-body capacitance and the second nonlinear capacitance is a source-to-body capacitance.

9. The apparatus of claim 1 further comprising a first capacitive element wherein the first electronic device is a first RF switch, which is coupled to the first capacitive element.

10. The apparatus of claim 1 wherein the capacitance compensation control circuit is further configured to adjust the first compensation capacitance using the first compensation control signal to substantially linearize the first nonlinear capacitance.

11. The apparatus of claim 1 wherein the first nonlinear capacitance compensation circuit comprises a varactor diode having the first compensation capacitance.

12. The apparatus of claim 11 wherein the capacitance compensation control circuit is further configured to adjust the first compensation capacitance via a varactor diode bias signal, which is substantially isolated from the first electronic device.

13. The apparatus of claim 1 wherein the capacitance compensation control circuit is further configured to adjust the first compensation capacitance based on at least a first system factor.

14. The apparatus of claim 1 wherein the capacitance compensation control circuit is further configured to adjust the first compensation capacitance based on a piece-wise correction function.

15. An apparatus comprising a first nonlinear capacitance compensation circuit, a capacitance compensation control circuit, and a plurality of electronic devices coupled in series between a first connection node and a second connection node, wherein:

the plurality of electronic devices comprises a first electronic device, which has a first nonlinear capacitance and is coupled to the first nonlinear capacitance compensation circuit;

the first nonlinear capacitance compensation circuit has a first compensation capacitance and is configured to receive a first compensation control signal;

the capacitance compensation control circuit is configured to adjust the first compensation capacitance using the first compensation control signal to at least partially linearize the first nonlinear capacitance;

each of the plurality of electronic devices has a corresponding one of a plurality of nonlinear capacitances;

the first nonlinear capacitance compensation circuit is coupled between the first connection node and the second connection node; and

the capacitance compensation control circuit is further configured to adjust the first compensation capacitance to at least partially linearize at least one of the plurality of nonlinear capacitances.

74

16. The apparatus of claim 15 wherein:

the apparatus further comprises a plurality of nonlinear capacitance compensation circuits coupled in series, such that each of the plurality of electronic devices is coupled to a corresponding one of the plurality of nonlinear capacitance compensation circuits;

the plurality of nonlinear capacitance compensation circuits comprises the first nonlinear capacitance compensation circuit;

each of the plurality of nonlinear capacitance compensation circuits has a corresponding one of a plurality of compensation capacitances; and

the capacitance compensation control circuit is further configured to adjust at least two of the plurality of compensation capacitances to at least partially linearize at least two of the plurality of nonlinear capacitances.

17. The apparatus of claim 16 further comprising a fine nonlinear capacitance compensation circuit coupled between the first connection node and the second connection node, wherein:

the plurality of compensation capacitances are coarse compensation capacitances;

the fine nonlinear capacitance compensation circuit has a fine compensation capacitance; and

the capacitance compensation control circuit is further configured to adjust the fine compensation capacitance to further partially linearize at least a portion of the plurality of nonlinear capacitances.

18. The apparatus of claim 16 wherein the plurality of electronic devices comprises a plurality of amplifier stages coupled in series between the first connection node and the second connection node.

19. The apparatus of claim 16 wherein the plurality of electronic devices comprises a plurality of sub-switches coupled in series between the first connection node and the second connection node.

20. An apparatus comprising:

a first electronic device having a first nonlinear capacitance and coupled to a first nonlinear capacitance compensation circuit;

a first replica circuit;

the first nonlinear capacitance compensation circuit having a first compensation capacitance; and

a bias circuit configured to provide a first bias signal to the first electronic device and further provide the first bias signal to the first nonlinear capacitance compensation circuit, which is configured to adjust the first compensation capacitance based on the first bias signal and the first replica circuit to at least partially linearize the first nonlinear capacitance.

21. The apparatus of claim 20 wherein:

the first electronic device further has a second nonlinear capacitance and is further coupled to the first nonlinear capacitance compensation circuit;

the first nonlinear capacitance compensation circuit further has a second compensation capacitance; and

the bias circuit is further configured to provide a second bias signal to the first electronic device and further provide the second bias signal to the first nonlinear capacitance compensation circuit, which is configured to adjust the second compensation capacitance based on the second bias signal to at least partially linearize the second nonlinear capacitance.
